LIST OF TABLES (Continued)

POLYMOOG SYNTHESIZER SPECIFICATIONS

SOUND SOURCES

No. of Oscillators	2 (71-pitch ranks; slaved to precision VCO)
Articulators	142 (VCA and VCF for each key)
Frequency Range	E_1-D_7, 71 note keyboard: pitch ribbon and external frequency control give maximum of ± 1 octave pitch control
Pitch Stability	± 0.2% (± 1/3 cent)
Pitch Ribbon Range	± 7 semitones minimum, ± 11 semitones maximum
Fine Tune Range	± 1 semitone
Beat Tune Range	± 1/4 semitone
Sawtooth Rank Tune	± a Major sixth
Sawtooth Rank Footage	4′ and 8′
Rectangular Rank Footage	8′ and 16′
Waveshape Select	Sawtooth, rectangular or both. Switchable for upper or lower keyboard or both

VOICES

Number	8 programmed, 1 variable
Voice Modification Controls	Sections switchable from preset to variable individually; Sawtooth rank tune, Sawtooth FM Rectangular FM/PM, Rectangular shape 1, mod, Sawtooth mix, Loudness contour, Resonators, VCF
Master Gain Controls	AUX, DIRECT, MODE RES, VCF

VOICES (Continued)

DIRECT	Direct channel output, 600 Ohms, 0dBm
RES	Resonator output channel 600 Ohms, 0dBm
Accessories	± 15V, +5 VDC power for accessories

CONTROL INPUTS

S-TRIG	Indicates filter control cycle
SWELL	Voltage control output level of BAL MIX or MIX output, 5 volts for 30dB change
FILTER	Voltage control of VCF cutoff frequency, 0.64V per octave
MOD AMOUNT	Voltage control of modulation frequency and pulse width when appropriate front panel controls are in variable mode, 0 to 5V
PITCH	Voltage control of oscillator frequency. Tip of jack controls both oscillators simultaneously. Stereo ring controls the frequency of rectangular rank separately 0.9V/ octave
EXT SYN	Switch input to control ON and OFF of S-TRIG OUT and KEYBOARD OUT
TRIG MODE	Switch input to determine single or multiple trigger mode S-TRIG OUT

CONTROL INPUTS (Continued)

SUSTAIN	Switch input to control final decay when front panel final DECAY switch is in MAN position
GLIDE	Switch input to control KEYBOARD OUT, GLIDE ON, OFF
VCF, RES, AUX	0dBm

CONTROL OUTPUTS

S-TRIG	+15 to 0.00 volts either single or multiple trigger, determined by TRIG MODE input control
KEYBOARD OUT	Monophonic keyboard control voltage output for controlling external synthesizers
KEYBOARD SCALE	Adjusts keyboard output control voltage from 0.95 ± 0.03V to 1.2 ± 0.05V/ octave
GLIDE CONTROL	Varies portamento to time of keyboard control voltage

CONTROL OUTPUTS (Continued)

BAL MIX	XLR Balanced line 600 ohm output
MIX	Single ended mix output derived from BAL MIX connector; insertion of jacks automatically unbalances BAL MIX to provide single ended output, 600 ohms, 0dBm
VCF	Voltage controlled filter channel output, 600 ohms, 0dBm
PRE-MODE	Internal fixed filter channel output, 600 ohms, 0dBm

GENERAL

Power Consumption	95-130/190-260V 50-60Hz; 0.5/0.25A
Unit Weight	71 lbs (32kg)
Shipping Weight	100 lbs (46kg)
Unit Size	45-1/2 x 22-1/4 x 6 in. (116 x 54 x 16cm)
Shipping Size	49 x 27 x 9.5 in. (125 x 64 x 25cm)

POLYMOOG KEYBOARD SPECIFICATIONS

SOUND SOURCES

Number of Oscillators	2 (71-pitch ranks; slaved to precision VCO)
Articulators	142 (VCA's and VCF's for each key)
Frequency Range	E_1-D_7, 71 note keyboard: pitch ribbon and external frequency control give maximum of ± 1 octave pitch control
Pitch Stability	± 0.2% (± 1/3 cent)
Pitch Ribbon Range	± 7 Semitones minimum
Fine Tune Range	± 1 semitone
Beat Tune Range	± 1/4 semitone

VOICES

Number	14 programmed
Voice Controls	MODULATION RATE and AMOUNT, OCTAVE BALANCE (3), ATTACK (sustaining voices)
BASS FILTER	14 programmed; variable CUTOFF FREQUENCY and separate GAIN controls
MAIN OUTPUT	Nominal output level 0dBm (0.7 volts); output impedance-less than 3K
BASS OUTPUT	Nominal output level 0dBm (0.7 volts). Output impedance-less than 3K. Plugging into bass output automatically isolates bass signal from main output)

CONTROL INPUT JACKS

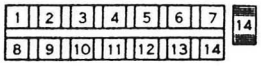
SWELL	30dB control 0 to 5 VAC. Input impedance-200K
FILTER	0.5 volts/octave input impedance. 1 megohm (for BRASS voices)
TRIGGER Mode	Switch to ground gives single selectable trigger or multiple trigger
PITCH	0.7 volts/octave
SUSTAIN	Switch to ground gives sustain
Accessory Power Outputs	± 15, +5 VDC at 100 mA available for each supply voltage

GENERAL

Power Consumption	95-130/190-260 VAC; 50-60Hz; 50 watts max
Unit Weight	60 lbs. (30kg)
Shipping Weight	90 lbs (41kg)
Unit Size	45-1/2 x 22-1/4 x 6 in. (116 x 54 x 16cm)
Shipping Size	49 x 27 x 9.5 in. (125 x 69 x 24cm)

CONTROL OUTPUT JACKS AND CONTROLS

Keyboard Control Voltage	Scale adjustable from 0.9 to 1.1 volts/ octave with rear panel SCALE potentiometer. RANGE adjustalbe ± 1-1/2 semitones
Trigger	S-TRIG (+15 to 0.0VAC): single/ multiple determined by TRIG MODE switch or footswitch



SECTION 1
GENERAL

1.1 INTRODUCTION

This manual supplies servicing and parts information for Polymoog Synthesizer Model 203A and Polymoog Keyboard Model 280A, manufactured by Moog Music Inc., 2500 Walden Avenue, Buffalo, New York 14225. Both instruments have a fully polyphonic standard keyboard allowing any number of notes to be played simultaneously.

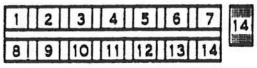
The manual is divided into two volumes. Volume I, consisting of 8 sections, provides circuit descriptions, troubleshooting and adjustments, and replacement parts lists. Volume II supplies schematics and printed circuit board part location diagrams.

Section 1 of Volume I provides general information for both Polymoog and Polymoog Keyboard. Sections 2 through 8 describe the instruments in "board-number-sequence". A quick reference table, Table 1-1, identifies the printed circuit boards with specific sections in Volume I. Since most adjustments are performed on printed circuit boards 7 and 9, illustrations are provided on the inside rear cover for convenience while performing these adjustments.

Volume I is bound and may be removed from the loose leaf binder and used separately by slightly turning and disengaging the plastic binder clips. The schematic section (Volume II) is then light enough to place on top of an opened Polymoog without damaging or bending any components.

The nomenclature on the Polymoog was changed after 2500 instruments were produced in order to identify the difference between the capabilities of the Polymoog Synthesizer, the most versatile instrument and the Polymoog Keyboard, a more simplified version with fourteen presets. Many photographs and explanations exist within this manual which refer to Polymoog Synthesizer Model 203A and the Polymoog Keyboard Model 280A. To make the distinction easier for service technicians who are new to the instruments, tabs in the schematic section (Volume II) are color coded in blue for those circuits which are unique to the Polymoog Keyboard. In addition, a reduced version of the front panel selector buttons has been added to each page of both Volume I and Volume II. This chart identifies the information pertaining to one of the instruments. If both front panel selector buttons appear on the same page, that particular text or illustration applies to both Polymoog and Polymoog Keyboard, as indicated in the example that follows.

POLYMOOG SYNTHESIZER



POLYMOOG KEYBOARD

1.2 PRINTED CIRCUIT BOARD ABBREVIATIONS

Table 1-1 lists each printed circuit board and associated abbreviation used throughout this service manual, including the board number and the section. Abbreviations used for interconnection follow in Table 1-2, along with a connector identification illustration, shown in Figure 1-1.

TABLE 1-1
PRINTED CIRCUIT BOARD ABBREVIATIONS

ABBREVIATION	PRINTED CIRCUIT BOARD OR CARD ASSEMBLY	POLYMOOG	POLYMOOG KEYBOARD	BOARD	SECTION
BAL	Balance Card	X	X		3
BY	Bypass Filter	X	X		3
CL	Left Hand Control Board	X		10	7
CL	Left Hand Control Board		X	10	7

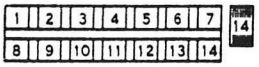


TABLE 1-1
PRINTED CIRCUIT BOARD ABBREVIATIONS (Continued)

ABBREVIATION	PRINTED CIRCUIT BOARD OR CARD ASSEMBLY	POLYMOOG	POLYMOOG KEYBOARD	BOARD	SECTION
CR	Right Hand Control Board	X		11	7
DIV	Divider Board	X	X	3	2
HFO	High Frequency Oscillator (Version 1)	X	X	1,2	2
HFO	High Frequency Oscillator (Version 2)	X	X	1,2	2
MBL	Low Mother Board	X	X	4	3
MBM	Medium Mother Board	X	X	5	3
MBH	High Mother Board	X	X	6	3
MOD_n	Modulator Card	X	X		6
MODE	Mode Selector	X		12	7
MODE	Master Voice Selector		X	12	7
PS	Power Supply (Moog)	X	X	13	8
PS	Power Supply (Faratron)	X		13	8
TC	Fixed and Resonant Filters	X		8	5
	Filter No. 1 - String	X		Part of 8	5
	Filter No. 2 - Piano	X		Part of 8	5
	Filter No. 3 - Organ	X		Part of 8	5
	Filter No. 4 - Harpsichord	X		Part of 8	5
	Filter No. 5 - Funk	X		Part of 8	5
	Filter No. 6 - Clavinet	X		Part of 8	5
	Filter No. 7 - Vibes	X		Part of 8	5
	Filter No. 8 - Brass (Version 1)	X		Part of 8	5
	Filter No. 8 - Brass (Version 2)	X		Part of 8	5
TC	Audio Board		X	8	5
	Filter No. 1		X	Part of 8	5
	Filter No. 2		X	Part of 8	5
TL	Reference Oscillator	X	X	7	4
TR	Voltage Controlled Filter	X		9	6
TR	Program Control Board		X	9	6
VOX	Vox Humana		X	14	5

1.3 CONNECTOR NOMENCLATURE

Due to the complexity of this instrument, no overall interconnecting wiring diagram exists. Therefore the interconnection abbreviations and description (Table 1-2) and the connector identification system (Figure 1-1) provide information on how each control and printed circuit board are assembled together.

The first digit (first two digits if the board number is above ten) is the board number, the second number is the connector number on that board and the number after the dash is the pin number within that connector.

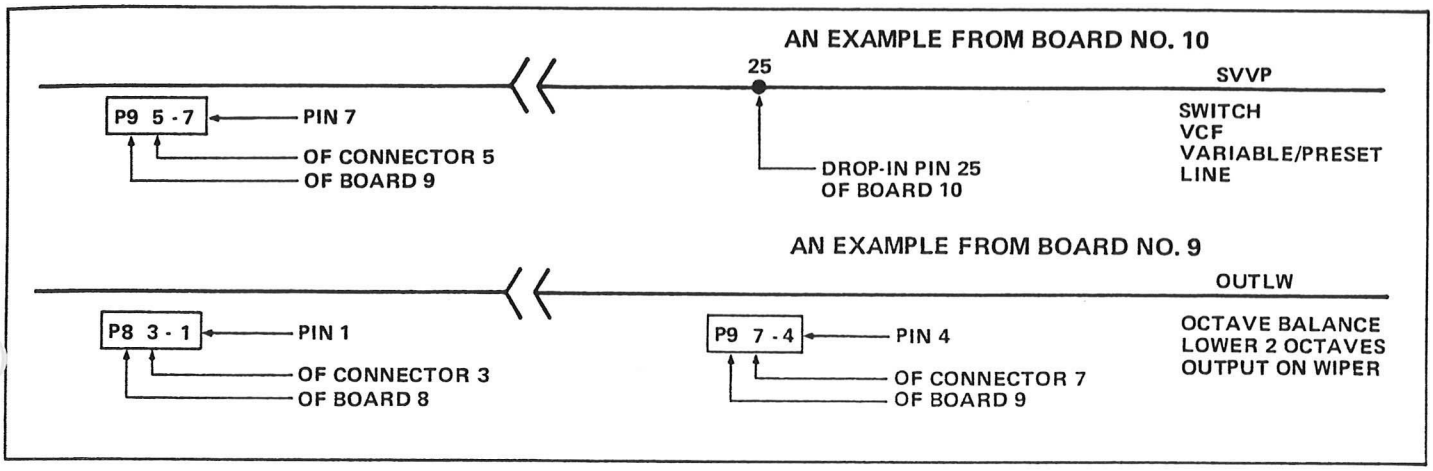

FIGURE 1-1 CONNECTOR IDENTIFICATION SYSTEM

TABLE 1-2
INTERCONNECTION ABBREVIATIONS

Buss ..... indicates common signal to modulator cards (via mother boards or common line to keyboard)
Pot..... indicates a voltage or current to or from a control (potentiometer)
Potentiometric.. indicates a variable control signal
Switch ..... indicates a TTL control line which is activated by a momentary switch (to ground)

ABBREVIATION	DESCRIPTION
A1	Coded binary output No. 1
A2	Coded binary output No. 2
B	BANDPASS mode for RESONATORS
BAL	Balance level from the balance card
BID	BEAT (rate) indicator drive
BIR	BEAT (rate) indicator return
BRITBH	Brightness buss - high (octaves 5 and 6)
BRITBL	Brightness buss - low (octaves 1 and 2)
BRITBM	Brightness buss - medium (octaves 3 and 4)
C	Control lines (gates) of CMOS packs

TABLE 1-2
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
CL No. 1 DECAY	Clock (decay) input from RECTANGULAR RANK
CL No. 2 (PW No. 2)	Clock (audio) input for the RECTANGULAR RANK
CL No. 3 (PW No. 1)	Clock (audio) input for SAWTOOTH RANK
CLK	Clock
CLKC1	Clock control for high frequency oscillator (No. 1) RECTANGULAR RANK
CLKC2	Clock control for high frequency oscillator (No. 2) RECTANGULAR RANK
CLR	Clock return line
CLR1	Clock return to phase comparator from divider - oscillator (No. 1) SAWTOOTH RANK
CLR2	Clock return to phase comparator from divider - oscillator (No. 2) RECTANGULAR RANK
CNTM	Contour and unbalanced mother board output
CSTI	Contour S-TRIG INPUT control line
D	Data line
DECPT	DECIMAL POINT (PART-FULL) buss line
DLLBH	Drive level limit buss of highest two octaves (5 and 6)
DLLBL	Drive level limit buss of lower two octaves (1 and 2)
DLLBM	Drive level limit buss of medium two octaves (3 and 4)
E	Equalization mode for RESONATORS (not connected)
EDIRO	External DIRECT OUTPUT line
EFMB	External frequency MODULATION AMOUNT drive buss
EFMC	External frequency MODULATION AMOUNT control INPUT line
ERES	External RESONATOR INPUT line
ESOO	KEYBOARD control ON/OFF for external Synthesizer keyboard circuit
EVCF	External VCF INPUT line
EXFIL	External FILTER INPUT line
EXI	External AUXILIARY INPUT line
EXIT	External AUXILIARY INPUT from top of pot line
EXIW	External AUXILIARY INPUT from pot wiper
FIL	Filter line from modulator VCF capacitors
FIL BRIGHT	Filter brightness line
FOOT	Foot SUSTAIN level
FTSUBH	Foot SUSTAIN for mother board buss-high (octaves 5 and 6) final decay
FTSUBL	Foot SUSTAIN for mother board buss-low (octaves 1 and 2) final decay
FTSUBM	Foot SUSTAIN for mother board buss-medium (octaves 3 and 4)
GLEX	External GLIDE ON/OFF control line
GS	General strobe output
GS	+15 volt DC supply ground sense line from power supply
H	HIGH PASS mode for RESONATORS
I	Inputs of CMOS switch packs
IDLA	Indicator lamp - "1" bit
IDLB	Indicator lamp - "2" bit

TABLE 1-2
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
KBBH	Keyboard bottom of the high resistor string
KBBL	Keyboard bottom of the low resistor string
KBLLB	Keyboard lowest level buss
KBBS	Keyboard buss for monophonic keyboard control voltage
KBEX	External KEYBOARD OUTPUT drive signal buss
KBHDB	KEYBOARD high (UPPER) octaves (5 and 6) DECAY RATE buss line
KBHLB	Keyboard highest level buss
KBLDB	KEYBOARD LOWER octaves (1 and 2) DECAY RATE buss line
KBMDB	KEYBOARD MEDIUM octaves (3 and 4) DECAY RATE buss line
KBSC	External KEYBOARD SCALE control line
KBTH	KEYBOARD top of the high resistor string
KBTL	KEYBOARD top of the low resistor string
KCEX	KEYBOARD control ON/OFF for external Synthesizer keyboard circuit
KSTR	KEYBOARD S-TRIG OUTPUT line
KTSM	KEYBOARD TRIGGER MODE SINGLE/MULTIPLE from the external rear panel jack
L	LOW PASS mode for RESONATORS
LIMIT	Drive level limit for SUSTAIN pedal
MACG	Modulation amounts contour generator for the string preset
MBBL	Mother board buss lines
MXO1	MIX OUTPUT No. 1
MXO2	MIX OUTPUT No. 2
MXO3	MIX OUTPUT No. 3
O	Outputs of CMOS switch packs
OS2C	Oscillator No. 2 (input) control line from rear panel external PITCH for rectangular rank
OSC1	Oscillator No. 1 high frequency output for SAWTOOTH RANK
OSC2	Oscillator No. 2 high frequency output for RECTANGULAR RANK
OSEXC	Oscillator external control input line labeled PITCH for both RECTANGULAR and SAWTOOTH RANK
OUT No. 1	Current output No. 1 from modulator cards for SAWTOOTH RANK
OUT No. 2	Current output No. 2 from modulator cards for RECTANGULAR RANK
OUTH	OCTAVE BALANCE slider drive high (octaves 5 and 6) from high mother board output
OUTHW	OCTAVE BALANCE slider drive high (octaves 5 and 6) output on wiper
OUTL	OCTAVE BALANCE slider drive low (octaves 1 and 2) from low mother board output
OUTLW	OCTAVE BALANCE low (octaves 1 and 2) output on wiper
OUTM	OCTAVE BALANCE slider drive medium (octaves 3 and 4) from medium mother board output
OUTMW	OCTAVE BALANCE medium (octaves 3 and 4) output on wiper
P1	STRING (10 volt) preset drive line
P2	PIANO (10 volt) preset drive line
P3	ORGAN (10 volt) preset drive line

TABLE 1-2
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
P4	HARPSICHORD (10 volt) preset drive line
P5	FUNK (10 volt) preset drive line
P6	CLAVINET (10 volt) preset drive line
P7	VIBES (10 volt) preset drive line
P8	BRASS (10 volt) preset drive line
PBADW	Pot BALANCE DIRECT wiper output line
PBAPT	Pot BALANCE DIRECT wiper output line
PBAPW	Pot BALANCE preset (MODE) wiper output line
PBART	Pot BALANCE RESONATOR top drive line
PBARW	Pot BALANCE RESONATOR wiper output line
PBRIN	Potentiometric brightness node
PCAM	Pot for CONTOUR amount (not used)
PCAMIN	Potentiometric CONTOUR AMOUNT (oscillator No. 1) SAWTOOTH RANK node
PCAMN	Potentiometric CONTOUR AMOUNT node
PCAT	Pot for CONTOUR ATTACK time
PCATN	Potentiometric CONTOUR ATTACK time node
PCDE	Pot for CONTOUR DECAY
PCDEN	Potentiometric CONTOUR DECAY time node
PCSU	Pot for CONTOUR SUSTAIN
PCSUN	Potentiometric CONTOUR SUSTAIN level node
PFMIN	Potentiometric FREQUENCY MODULATION RATE node for SAWTOOTH RANK
PFMZN	Potentiometric FREQUENCY MODULATION/PHASE MODULATION RATE node for RECTANGULAR RANK
PKAT	Pot for KEYBOARD ATTACK
PKATN	Potentiometric KEYBOARD ATTACK node
PKBS	Pot for KEYBOARD SUSTAIN
PKBSN	Potentiometric KEYBOARD SUSTAIN node
PKDH	Pot for KEYBOARD DECAY - high (UPPER four octave) drive
PKDHN	Potentiometric KEYBOARD DECAY RATE - high (UPPER four octave) node
PKDL	Pot for KEYBOARD DECAY - LOWER two octave drive
PKDLN	Potentiometric KEYBOARD DECAY RATE - LOWER two octave node
PKDY	Pot for KEYBOARD DYNAMICS level
PKDYN	Potentiometric KEYBOARD DYNAMICS node
PKGL	Pot (external) KEYBOARD GLIDE
PKGLN	Potentiometric (external) KEYBOARD GLIDE node
PLCMN	Potentiometric clamp level modulator drive node
PO1TN	Potentiometric (oscillator No. 1) SAWTOOTH RANK TUNE node - variable mode only
PO1NTN	Potentiometric (oscillator No. 1) SAWTOOTH RANK TUNE node - preset mode only
POBT	Pot oscillators BEAT RATE voltage control line

TABLE 1-2
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
POEM1N	Potentiometric oscillator FREQUENCY MODULATION AMOUNT node for SAWTOOTH RANK
POFM2N	Potentiometric oscillator FREQUENCY MODULATION/PHASE MODULATION AMOUNT node for the RECTANGULAR RANK
POFT	Pot oscillators FINE TUNE voltage control line
PR	Preset (set)
PRF1A	Pot RESONATOR CUT OFF FREQUENCY (No. 1) LOW section
PRFZA	Pot RESONATOR CUT OFF FREQUENCY (No. 2) MID section
PRF3A	Pot RESONATOR CUT OFF FREQUENCY (No. 3) HIGH section
PRGA1	Pot RESONATOR GAIN amount line for (No. 1) LOW section
PRGA2	Pot RESONATOR GAIN amount line for (No. 2) MID section
PRGA3	Pot RESONATOR GAIN amount line for (No. 3) HIGH section
PRQ1	Pot RESONATOR Q (EMPHASIS) for (No. 1) LOW section
PRQ2	Pot RESONATOR Q (EMPHASIS) for (No. 2) MID section
PRQ3	Pot RESONATOR Q (EMPHASIS) for (No. 3) HIGH section
PRQ3	Pot RESONATOR GAIN amount line for (No. 3) HIGH section
PSHN	Potentiometric (pulse width) SHAPE high (octaves 5 and 6) node for RECTANGULAR RANK
PSLN	Potentiometric (pulse width) SHAPE LOWER (octaves 1 and 2) node for RECTANGULAR RANK
PSMN	Potentiometric (pulse width) SHAPE MEDIUM (octaves 3 and 4) node for RECTANGULAR RANK
PSWHN	Potentiometric SAWTOOTH (RANK MIX) level high (UPPER four octave) node
PSWLN	Potentiometric SAWTOOTH (RANK MIX) level LOWER two octave node
PVBA	Pot VCF BALANCE line
PBAOT	Pot BALANCE DIRECT top drive line
PVCO	Pot for VCF CUT OFF
PVCON	Potentiometric VCF CUT OFF node
PVEM	Pot for VCF EMPHASIS
PVEMN	Potentiometric VCF EMPHASIS node
PVKB	Pot for VCF KEYBOARD AMOUNT
PVKBP	Potentiometric VCF keyboard preset drive node
PVMA	Pot for VCF modulation AMOUNT
PVMAN	Potentiometric VCF modulation AMOUNT node
PVMR	Pot for VCF modulation RATE
PVMRN	Potentiometric VCF modulation RATE node
PVSH	Pot for VCF SAMPLE and HOLD
PVSHN	Potentiometric VCF SAMPLE and HOLD node
PW No. 2	Pulse width control (No. 2) line for the RECTANGULAR RANK
PWMHN	Pulse width AMOUNT of the high (UPPER four octaves) of the RECTANGULAR WAVESHAPE/MODULATION section
PWMLN	Pulse width AMOUNT of the (LOWER two octaves) of the RECTANGULAR WAVESHAPE/MODULATION section

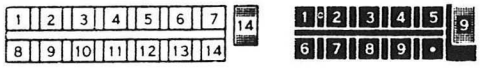

TABLE 1-2
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
PWSHB	Pulse width SHAPE for highest buss (octaves 5 and 6) of the RECTANGULAR WAVESHAPE/MODULATION section
PWSLB	Pulse width SHAPE for lower buss (octaves 1 and 2) of the RECTANGULAR WAVESHAPE/MODULATION section
PWSMB	Pulse width SHAPE for medium buss (octaves 3 and 4) of the RECTANGULAR WAVESHAPE/MODULATION section
Q	Flip flop output
$\overline{Q}$	Inverted flip flop output
$\overline{Q}$2	Inverted flip flop output No. 2
$\overline{Q}$3	Inverted flip flop output No. 3
$\overline{Q}$4	Inverted flip flop output No. 4
RIBB	Ribbon pitch controller voltage input line
RP1	Reset preset buss line
SCL14	Switch clock oscillator No. 4′ SAWTOOTH RANK
SCL18	Switch clock oscillator No. 8′ for SAWTOOTH rank
SCL26	Switch clock oscillator No. 2 16′ for RECTANGULAR RANK
SCL28	Switch oscillator No. 2 8′ for RECTANGULAR RANK
SFTEX	Switch external foot switch SUSTAIN for final decay drive line
SKH	Switch for VCF KEYBOARD high (UPPER) drive
SKL	Switch VCF KEYBOARD LOWER drive line
SK01H	Switch KEYBOARD WAVESHAPE (oscillator No. 1) for the (high) UPPER four octaves of the SAWTOOTH RANK
SK02H	Switch KEYBOARD WAVESHAPE (oscillator No. 2) for the (high) UPPER four octaves of the RECTANGULAR RANK
SK01L	Switch KEYBOARD WAVESHAPE (oscillator No. 1) for LOWER two octaves of the SAWTOOTH RANK
SK02L	Switch KEYBOARD WAVESHAPE (oscillator No. 2) for LOWER two octaves of the RECTANGULAR RANK
SKTM	Switch KEYBOARD VCF to mode (ALL/SPLIT)
SP1	Switch preset No. 1 for STRINGS
SP2	Switch preset No. 2 for PIANO
SP3	Switch preset No. 3 for ORGAN
SP4	Switch preset No. 4 for HARPSICHORD
SP5	Switch preset No. 5 for FUNK
SP6	Switch preset No. 6 for CLAVINET
SP7	Switch preset No. 7 for VIBES
SP8	Switch preset No. 8 for BRASS
SP9	Switch preset No. 9 VARIABLE
SPB1	Switch preset bit "1"
SPB2	Switch preset bit "2"
SPB3	Switch preset bit "3"
SPLFR	Switch preset LOCK FREE line
SREH	Switch KEYBOARD RESONATOR AND MODE high (UPPER) four octaves

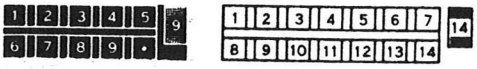

TABLE 1-2
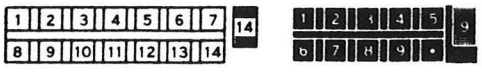
INTERCONNECTION ABBREVIATIONS (Continued)

ABBREVIATION	DESCRIPTION
SREL	Switch KEYBOARD RESONATOR AND MODE LOWER two octaves
SREM1	Switch RESONATOR BANDPASS mode
SREM2	Switch RESONATOR equalization BANDPASS mode
SREM3	Switch RESONATOR HIGHPASS mode
SREM4	Switch RESONATOR LOW PASS mode
SRE00	Switch RESONATORS ON/OFF
SREV	Switch KEYBOARD RESONATOR AND MODE VARIABLE (not used)
SVCH	Switch VCF high UPPER (four octaves) KEYBOARD audio control line
SVCL	Switch VCF LOWER (two octaves) KEYBOARD audio control line
SVFTO	Switch front panel SUSTAIN final decay drive line ON/OFF
SV00	Switch VCF ON/OFF
SVVP	Switch VCF VARIABLE/PRESET
SWLBH	SAWTOOTH RANK level buss high (octaves 5 and 6)
SWLBL	SAWTOOTH RANK level buss LOW (octaves 1 and 2)
SWLBM	SAWTOOTH RANK level buss medium (octaves 3 and 4)
TRGH	Trigger buss high for upper 4 octaves of monophonic keyboard
TRGL	Trigger buss for lower two octaves of monophonic keyboard
VCC	5-volt power supply line
VCFO	VCF output line
VCH	Audio reference voltage of 4.85VDC
VCHR	VCH reference voltage to mother board
VP1	VARIABLE PRESET line
V + S	+15-volt DC supply sense line from power supply
XX	Common drive line
YY	Common drive line
ZZ	Common drive line for CMOS 4007 packs



1.4 GENERAL

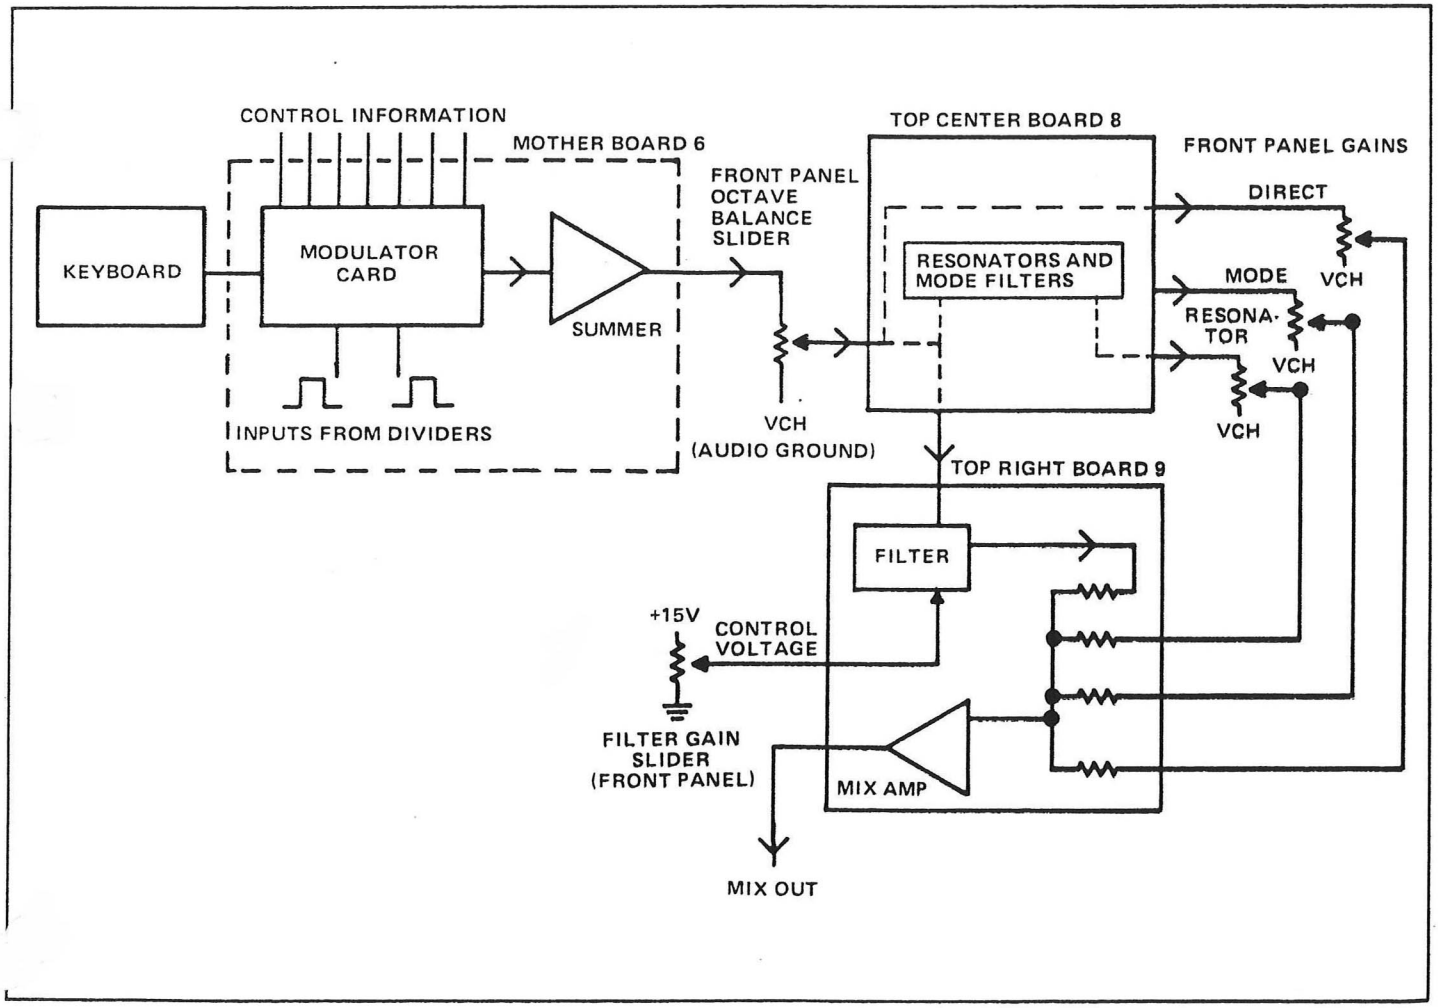
The Polymoog and Polymoog Keyboard are ılly polyphonic keyboards taking both into the realm of electronic pianos, organs, vibes, brass and string effects. Control of these instruments is effected by the keyboard and the front panel control assembly, consisting of a variety of potentiometers, switches, and associated circuitry. Figure 1-2 is a simplified block diagram of the Polymoog and Polymoog Keyboard systems.

The overall description of the instrument that follows was developed specifically for the Polymoog Synthesizer. Many principals apply to the Polymoog Keyboard but reference should be made to the individual printed circuit board description for further information.

A chart depicting Polymoog signal flow is included for additional information.

1.5 POWER SUPPLY

The power supply is comprised of three precision regulated power sections providing +5, +15 and -15 VDC. Adjustments for the supply voltages are located on the power supply printed circuit board which may be removed as a subassembly for servicing. The individual power supply sections have remote ground and supply sense lines which are applied directly to the left and right hand control panel boards (CL and CR) of the front panel control assembly. The sense lines for the +5 and -15 VDC supplies are terminated at the CL and CR boards which in turn distribute power to other boards in the system. The +15 VDC sense line terminates on the reference and modulation oscillator waveshape and keyboard control board (TL) because the reference oscillators located on the TL board are sensitive to +15 VDC supply voltage variations. Each individual power supply section incorporates short circuit and over voltage circuit protectors. The over voltage circuit protectors, called transorbs,



POLYMOOG SIGNAL FLOW CHART

are located on the control boards and clip off excessive voltage transients. Should a very high voltage occur accidentally on the power supply line, these circuit protectors go to a dead short condition, shutting down the supply and protecting the system from a massive burn out.

In addition to the three main supply voltages provided by the main power supply, there are two secondary supply voltages provided by two regulators on the CR board. Voltages of +4.85 and -5.5 VDC are derived from the +5 and -15 VDC voltage rails respectively and adjustments for these two supplies are located on the CR board. The +4.85 VDC voltage serves as the internal audio reference rail. Final output audio voltages are re-referenced to ground via an output transformer or directly via capacitors. The +4.85 and -5.5 VDC rails provide power to the main modulator/generator section and several other functio

The +5 VDC supply provides power for the T (transistor-transistor logic) and LEDs (light emitti diodes) throughout the instrument, the +15 VDC r drives the CMOS circuitry, and, with a few exceptio the operational amplifiers are powered from both + and -15 VDC rails. All high voltage is covered a located at the left rear of the instrument near t power switch. This cover should not be remov unless it is necessary to replace the fuses and if fu are replaced, install this cover immediately to preve possible shock. Otherwise, accessible circuit points a free of shock hazard. The power supply connectors various boards in the system may be disconnect without damaging the remaining connected boards provide a convenient way of locating power supp shorts should they occur.

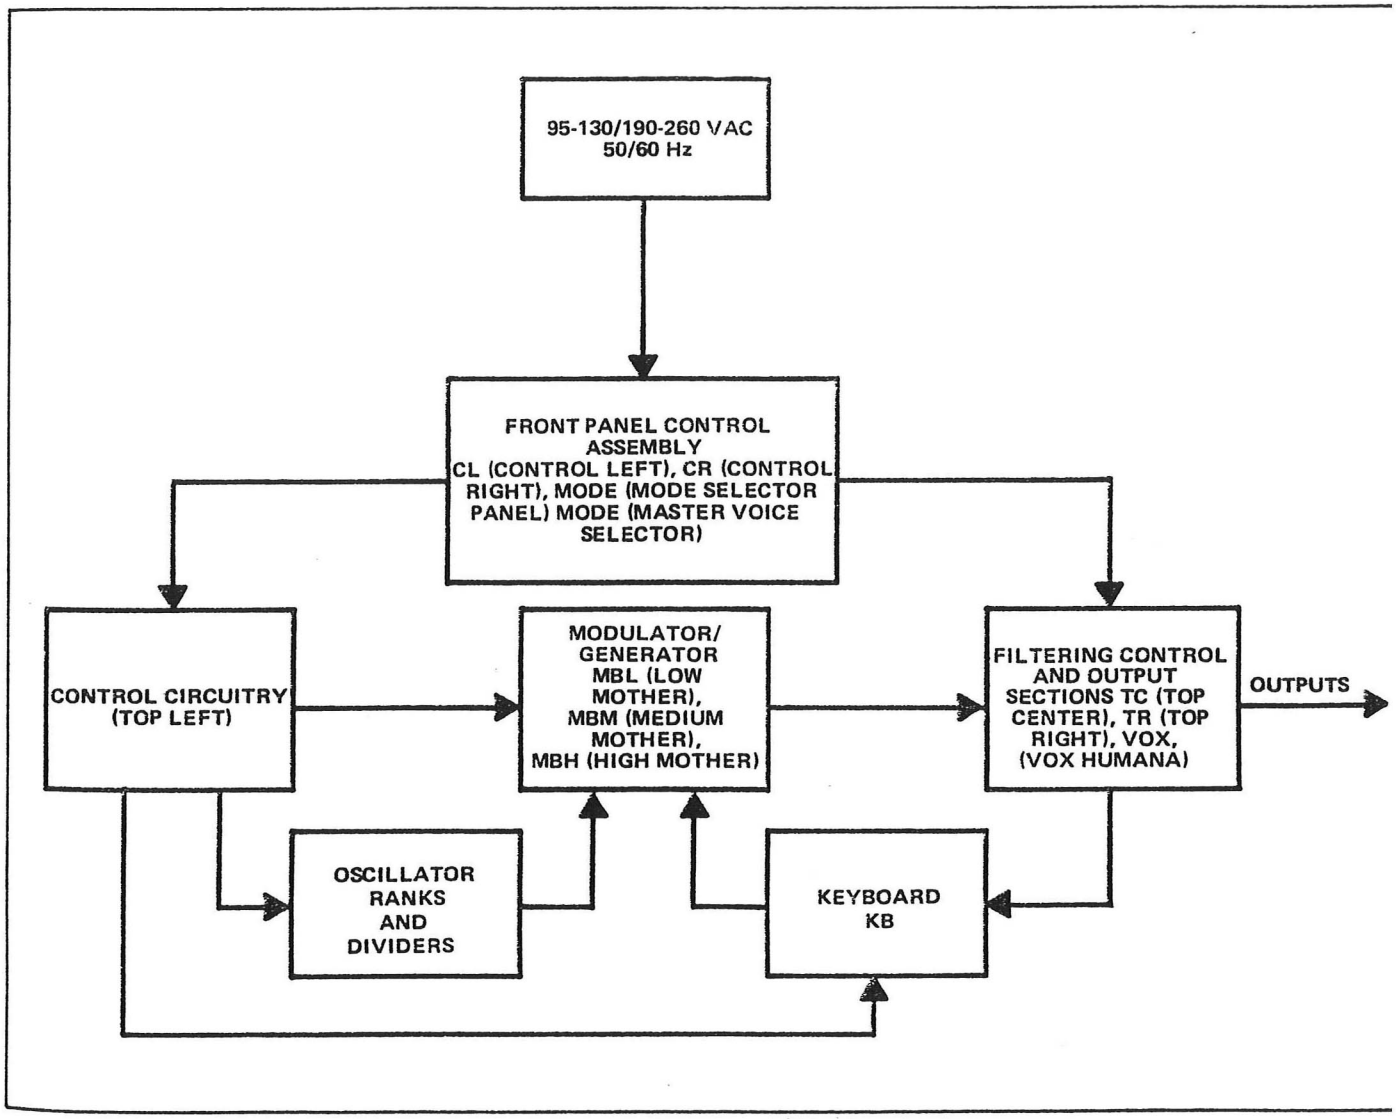


FIGURE 1-2. POLYMOOG AND POLYMOOG KEYBOARD SIMPLIFIED BLOCK DIAGRAM

1.6 FRONT PANEL CONTROL ASSEMBLY

The front panel control assembly provides control currents and digital logic levels to the system whose values are determined by its control potentiometers and switches. Table 1-3 contains a list of front panel controls with their associated control function and printed circuit board. Referring to the detailed block diagram, Volume II, note that the control panel assembly consists of six major parts: left and right hand control panel potentiometers and printed circuit boards located under the front panel extrusion, ribbon pitch controller and mode selector control (master preset) mounted on the center extrusion.

Digital logic levels are derived directly from the states of TTL latching circuits which are electronic equivalents of multiposition switches. These multiflop latches are set to the desired state by depressing the appropriate momentary contact pushbutton. Associated with each of these multiflop latches are LED indicators. Each time a master preset button is activated, these latches, located on the control boards, are positioned to a set of preselected states via diodes on the control boards. At any time after a master preset button is released, this particular preset state may be overridden by depressing one of the individual buttons of the set associated with a particular latch. Thus, the status of these latches may be changed in a preset selected manner by the mode selector master preset or set to the desired state individually using the buttons associated with that particular latch. Refer to Figure 1-3.

In addition to latches which provide digital control signals directly to the system, there are a set of two-state latches which determine whether a particular linear control variable is determined by a preset resistor network or by a front panel potentiometer. These latches are called VAR-PRE latches. When any one of the eight master modes is selected by depressing one of the eight mode selector switches in the master preset section, all of these latches are set to the PRE state via the RP1 buss line. If No. 9 pushbutton is depressed, all of these latches are set to the VAR state via the VP1 buss line. As explained previously, each of these VAR-PRE latches may be individually set to the desired state by depressing the appropriate button associated with that particular latch. In general, these VAR-PRE latches control a number of specific functions at one time. For example, the VAR-PRE selector associated with frequency modulation (FM) on the left hand control panel controls four specific functions, two independent FM rates and FM amounts. When a particular section is in the PRE mode, a set of internal program resistors driven by preset drive lines and tied together in

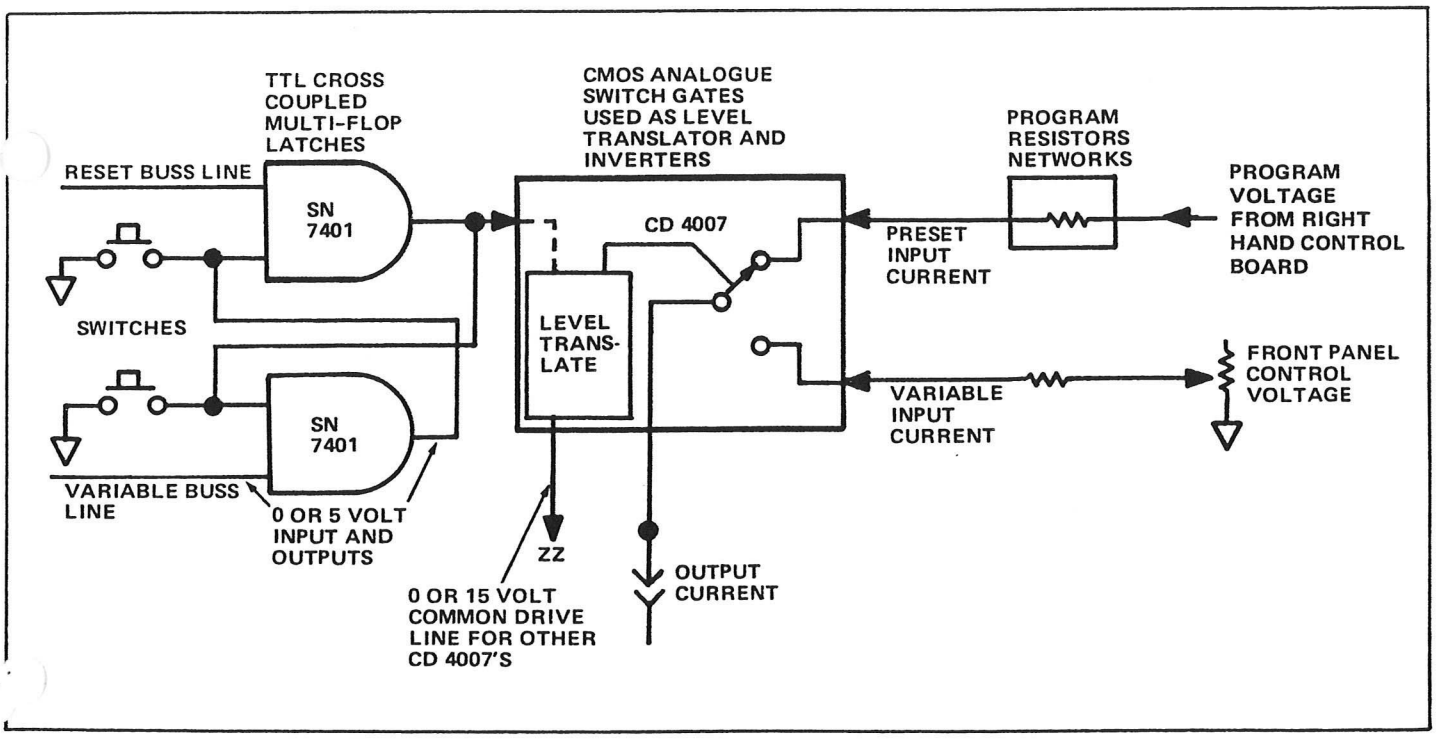

FIGURE 1-3 TYPICAL CONTROL BOARD SEQUENCE

common on the output side provide program currents for the active preset to a set of CMOS analog switch gates. Associated with each linear function control is an individual CMOS switch. The group of CMOS switches associated with a particular block, controlled by one of the VAR-PRE latches, route the program currents to an appropriate control summing node located on either the TL or TR circuit boards.

The FINE TUNE and BEAT rate controls located on the far left of the panel provide tuning control and are active at all times. Figure 1-7 shows the individual controls associated with each functional block controlled by the VAR-PRE latches. The front panel slide potentiometers act as voltage dividers and in general, are strapped between ground and +15 VDC. However, six controls (frequency modulation and amount of shape modulation controls) are driven between ground and a potential determined by circuitry on the TR board, which in turn may be controlled via the MOD AMT connector on the rear panel.

The center panel mode selector control (master preset section) utilizes circuitry located on the CR board to provide control signals for setting the various multiflop latches described previously. Information from the mode selector control pushbuttons is encoded to binary form and latched by TTL circuitry on the CR board. This encoded binary representation of the active preset is sent to several places in the system and then decoded back to linear code for driving the P lines which drive the program resistors. In addition, the binary encoded signal drives a seven-segment decoder (located on the mode selector control board) to provide drive for the seven-segment numeric display producing a visual indication of the active preset.

The "." pushbutton on the mode selector control toggles a flip-flop which defeats the RP1 action explained previously. When the decimal point indicator is illuminated, depressing one of the eight preset pushbuttons does not reset the VAR-PRE latches and these latches remain in the state at which they were last set. Thus, the decimal point pushbutton serves the purpose of a cancel defeat.

The RIBBON PITCH CONTROLLER, located in the center of the panel, is a linear resistance element with approximately plus and minus 5 VDC applied to the top and bottom of the ribbon. When the ribbon is depressed, a metallic element above the resistance element contacts the resistor and provides a voltage, which may be continuously varied by moving the finger across the ribbon element. This voltage is applied to the reference oscillators located on the TL board. This ribbon element plugs into the CL board and may be removed from the front panel without disassembling the front panel assembly.

The resonator controls located on the right hand panel are direct circuit audio controls as opposed to voltage controls. The MASTER GAIN CONTROLS and OCT BAL controls located on the far left are also direct audio controls with the exception of the VCF master gain control which is a voltage control.

In summary, the front panel control assembly serves as an overall systems controller interface converting and routing the settings of switches and potentiometers controlled by the player to the appropriate electronic control signals.

1.7 CONTROL CIRCUITRY (Refer to Figure 1-4)

The control circuitry is located on the TL board and: (1) converts and scales control currents from the front panel control assembly to voltages required by the modulator/generator section; (2) generates a set of d-c carrier buss line drives to the keyboard under control of signals provided by the front panel control assembly; and (3) generates reference oscillator signals at approximately 1.3 kHz with phase lock circuitry to control the sawtooth and rectangular rank oscillators.

The first item includes three modulation oscillators with associated voltage controlled amplifiers (two used for frequency modulation and one for pulse width modulation) to provide a rectangular pulse width, sawtooth level, drive level limit and decay rate functions.

The modulation oscillators and their associated voltage controlled amplifiers determine the amount of modulation applied to various control points and are essentially identical. The oscillator employs a CA3080 integrated circuit as a current source to a capacitor whose voltage is buffered by a voltage follower driving a Schmitt trigger which switches the plus input of the CA3080, reversing the current flow to the capacitor. The equal rates of positive and negative integration are determined by bias current applied to the CA3080 controlled by rate function controls on the front panel assembly. The triangular output from the modulation oscillators drive another

CA3080 integrated circuit used as a voltage controlled amplifier. In this case, bias current applied to the CA3080 is multiplied by the triangular voltage applied to its voltage inputs resulting in an output current proportional to the product of bias current and voltage input. Modulation oscillator No. 2 drives its amount voltage controlled amplifier (VCA) at a higher level than the others, resulting in a rounding off of the waveform at the output of the VCA. This intentional rounding produces an approximate sinewave output, the input voltage characteristics of the CA3080 providing a "soft" limiting.

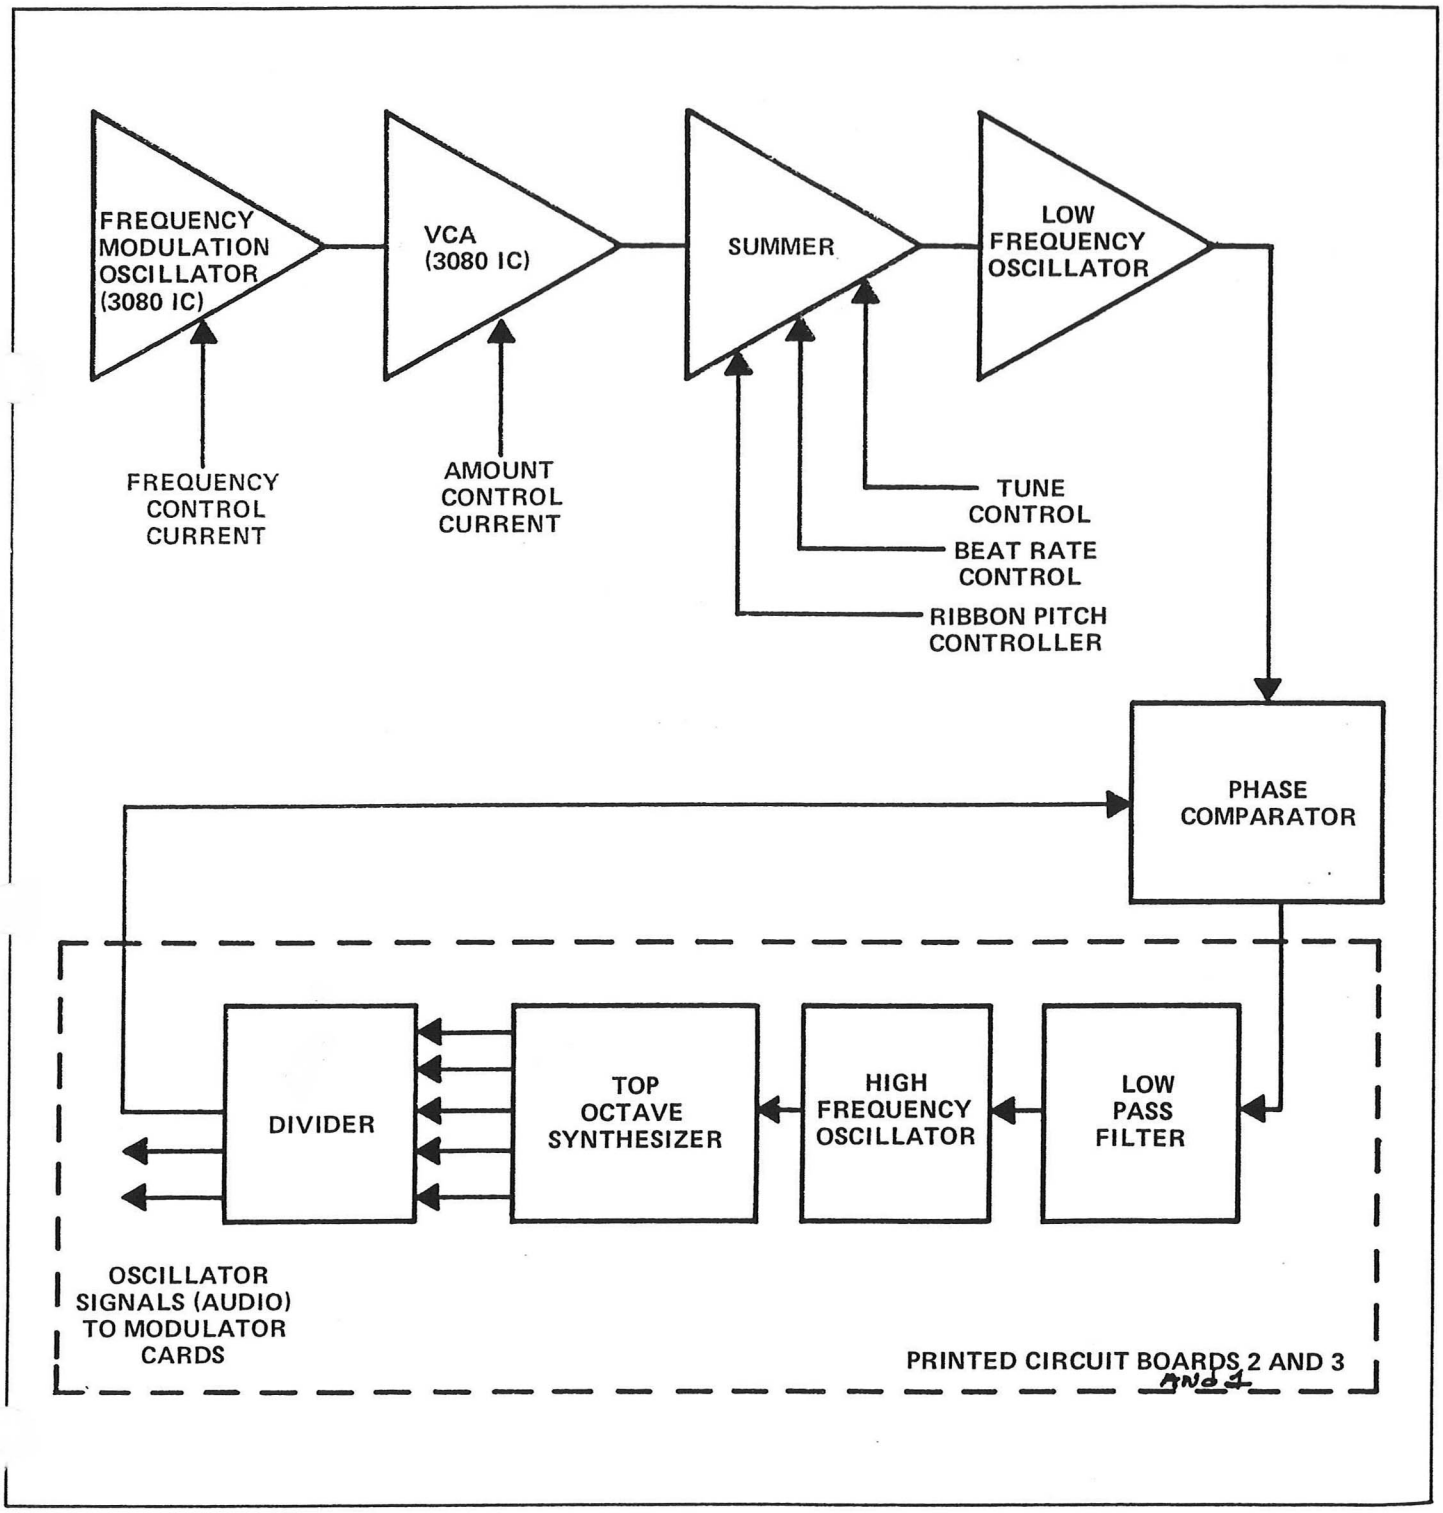

FIGURE 1-4 TYPICAL FLOW FOR RECTANGULAR RANK OSCILLATOR ON TOP LEFT BOARD NO. 7

The outputs of the modulation oscillator amount VCA are applied to two reference oscillators for frequency modulation and to the rectangular pulse width circuitry for frequency modulation and pulse width modulation effects, respectively. Simple operational amplifier circuits with bias trim control are used in the rectangular pulse width circuit to provide a d-c control voltage to the low, medium and high mother boards (MBL, MBM, and MBH) which contain the modulator/generator circuits. Currents for tuning control from the front panel control assembly are added to the current from the frequency modulation oscillator amount VCAs to provide a composite control signal for the reference oscillators.

The sawtooth level, drive level and decay controls are comprised of simple operational amplifier circuits with d-c bias trim adjustments and convert currents (provided by the front panel control circuitry) to d-c control voltages which are applied to the mother boards in the modulator/generator section.

The keyboard circuitry is best explained in conjunction with the keyboard itself. The Polymoog keyboard contains two independent sections, a polyphonic keyboard section and a monophonic keyboard section. The monophonic keyboard section is described in conjunction with the TR circuit board of the filtering and output sections. In the polyphonic keyboard section, depressing a key applies a composite signal to the mother board modulators controlling three basic sound generating functions; attack, sustain level and dynamics. The attack time and sustain level are controlled by the pulse width and pulse height, respectively, of a 20 kHz carrier pulse train. The dynamic control signal is a residual d-c voltage across a parallel RC network. With no key depressed, a d-c or static voltage is applied across this parallel RC network along with a carrier signal and when a key is depressed, this parallel RC network is released from its charging buss. After a certain key travel distance, the residual d-c potential applied to the top of the RC network is applied to the corresponding modulator on the mother board causing a "kick" in the loudness contour, the signal which basically turns the sound on and off. If a key is depressed very rapidly, the residual d-c voltage across the RC network is large and causes a correspondingly large "kick" in the loudness contour. If a key is depressed slowly, the original voltage across this RC network has decayed to a lower value causing a correspondingly lower or smaller "kick" in the loudness contour. As mentioned previously, when the top of the RC network is applied to the individual modulator board, attack, sustain level and dynamic information is conveyed on a single wire.

The low voltage sides of all 71 RC networks for all notes are tied together to the low level buss. The high voltage or charging buss is a composite d-c/a-c signal maintained at a constant peak potential. The front panel KB DYN control changes the d-c potential of the low level buss so that as this potential is raised, the minimum "kick" (a key depressed very slowly) applied to the contour generator increases. However, as this low level potential is raised, the difference in potential appearing across the RC network decreases resulting in a less dynamic sensitivity effect. In other words, a fixed control operating dynamic range is split between the fixed "kick" or lowest level provided by the potential on the lowest level buss and the dynamic head room.

The composite d-c/a-c signal appears as a voltage drive on the lowest level buss. Because of strong a-c coupling between the lowest level buss and the highest level buss (charging buss), the highest level buss is driven from a current source to provide an offset between the two busses. The peak detector and regulator associated with the highest level current source detects the peak level on this buss and regulates the current source so that the peak value is constant. This regulator takes effect whenever the lowest level is changed via the front panel KB DYN control or when the sustain level (determined by the carrier pulse height) is changed. The peak detector and regulator associated with the lowest level buss senses the peak level of the lowest level buss and, if this level should begin to exceed the level of the highest level buss, prevents any further increase in the lowest level potential. Increasing the sustain level (20 kHz pulse height) will reduce the baseline potential of the highest level buss via its associated peak detector and regulator.

An overall dynamic range is achieved or reached by a combination of a dynamic "kick," a minimum or fixed "kick " and a sustain drive. The complex interaction of these three controls is governed in a feedback fashion by the peak detectors and regulators. Since every electronic circuit has a maximum dynamic range and if various drive mechanisms are to be capable of achieving an essentially full dynamic range, some mechanism must be provided to force one of the mechanisms to "give" when another one is pushed toward its maximum. In the Polymoog, this is accomplished by limiting the minimum "kick" and/or the

dynamic effect as the sustain level is increased. Thus, if the sustain level is set at maximum, there will be no a-c "kick" related to dynamic effect. Intermediate control settings result in mixed modes which provide combinations of dynamic and sustained contours.

The third major section on the TL board contains two precision voltage controlled oscillators whose center frequencies are approximately 1.3 kHz and two phase comparators. High frequency voltage controlled oscillators which drive conventional top octave synthesizers are located on the high frequency oscillator boards of the divider and are synchronized to the reference oscillators using phase comparators. The reference oscillators are driven from precision temperature regulated exponential voltage-to-current converters. This overall system provides an extremely stable pitch control with precision exponential (constant volt/octave) control.

Synchronization of the high frequency oscillators with the reference oscillators is accomplished by comparing a divided down version of the high frequency oscillator output with the reference oscillator output in the phase comparator and driving the high frequency voltage controlled oscillator from the output of the phase comparator. This is a conventional phase-lock-loop configuration.

There are two basic modes of operation for the oscillator systems. In the FREE mode, both oscillator systems run completely independent. In the LOCK mode, both high frequency voltage controlled oscillators are slaved to sawtooth reference oscillator No. 1. However, the reference frequency for the second oscillator system is not the direct output of the first reference oscillator, but rather a phase modulated version of this reference oscillator signal. Thus, while both high frequency voltage controlled oscillators are slaved to reference oscillator No. 1, they may be phase modulated with respect to each other to provide choral effects and yet retain the advantages of locked operation, that is, zero relative frequency drift.

Extremely stable oscillators are required as it is very desirable to be able to set and maintain the two oscillators at very small frequency differences. The beat rate or frequency difference between the two reference oscillators is indicated by a front panel LED driven by the beat rate detector which is in turn driven by the two reference oscillators. This beat detector is a simple OR function between the two oscillators.

The phase comparators are edge triggered digital type phase comparators which do not lock on harmonics but require an exact frequency match on its two inputs for locking. Reference oscillator No. 1, the master oscillator, may be tuned over a plus or minus musical sixth by the RANK TUNE variable control on the front panel and both reference oscillators may be tuned over ±2 semitones by the FINE TUNE control. In addition, reference oscillator No. 2 may be tuned ±1/2 semitone by the BEAT control. Both oscillators are driven simultaneously over a plus or minus musical sixth by the ribbon PITCH CONTROLLER and the pitch of both oscillators may be varied simultaneously by applying a control signal to the rear panel PITCH input connector. The stereo ring on this jack permits pitch control of oscillator No. 2 only.

1.8 MODULATOR/GENERATOR

The modulator/generator section, consisting of the low, medium and high mother boards, performs the main signal generation in the Polymoog. Each mother board contains a number (24 for low and medium and 23 for high) of small plug-in modulator boards each containing a number of discrete components and a custom integrated circuit. In addition, each mother board contains a number of coupling capacitors, filter capacitors and an output summing amplifier. Voltages on control lines bussed in common to all modulator boards control basic parameters of sound generation, such as decay rate, pulse width, sawtooth amplitude, brightness or degree of filtering, final decay on-off and maximum contour level. Each plug-in modulator board contains the functions of a contour generator, a double VCA, 2-pole filter, final decay on-off and sawtooth and rectangular wave shaping. Each modulator board is driven by two capacitively a-c coupled audio oscillator inputs derived from the divider board. These two differentiated square waves are converted to a variable width pulse and a sawtooth waveform in the custom integrated circuit. When a key is depressed, a composite signal controlling attack, dynamic and sustain level information is transmitted to each modulator board. This composite drive signal is converted by the custom integrated circuit and a single capacitor into the desired contour which internally modulates, filters and combines two audio waveforms. The output from each modulator board is a differential current and corresponding outputs are bussed together and applied

directly to the summing node of the current-to-voltage converter operational amplifiers. Each mother board has a separate voltage output for a two octave section and these three outputs are summed directly together for a DIRECT output and applied to the voltage controlled filter, mode filters and resonators.

1.9 FILTERING AND OUTPUT SECTIONS

The filtering and output sections are contained on the voltage controlled filter and keyboard circuit board (TR) and fixed and variable resonant filter board (TC).

The TR circuit board contains three main circuit functions: (1) the voltage controlled filter with associated functions; (2) output drive and swell (loudness) control; and (3) the monophonic keyboard system.

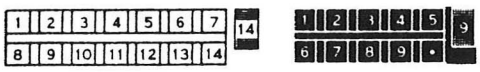
The voltage controlled filter has four sections with emphasis control and employs the patented Moog transistor ladder. The functions associated with this voltage controlled filter include the contour generator, sample and hold, triangular modulation, cutoff frequency, amount of keyboard feed and emphasis. As indicated in Volume II, a number of Polymoog functions are applied on a split keyboard basis. In particular, the audio signal applied to the voltage controlled filter may be derived from the bottom two octaves or the top four octaves via the lower-upper select circuitry controlled from KEYBOARD LOWER-UPPER pushbutton switches and their associated latches. After lower-upper selection, the gain of the VCF audio path is normalized by VCF gain select resistors since the level of the audio signals coming from the modulator/generator mother boards will vary from preset to preset. Emphasis or Q control of the filter is accomplished by using a CA3080 integrated circuit as a variable gain feedback element to the transistor ladder.

Contour generator operation consists of an initial attack, followed by an initial decay to a prescribed sustain level, followed by a final decay. If the final decay (foot sustain) for the polyphonic system is on (LOCK pushbutton depressed), the final decay for the filter contour generator will also be on and vice versa. The contour generator utilizes a LM555 integrated circuit as a basic control element and a CA3080 integrated circuit as a remotely controlled current device which charges or discharges an integrating capacitor at rates determined by currents provided by the front panel control assembly. Attack and decay currents are switched back and forth to the CA3080 using CMOS switches, depending upon whether the contour is in the attack or decay phase. The sustain level is a voltage derived from the front panel control current which sets an equilibrium point for the contour generator during the initial decay phase. That is, the contour initially attacks, then seeks the variable sustain level at the variable decay rate. When a key is raised, the sustain or equilibrium value is returned to zero and the contour generator seeks zero at the decay rate if the polyphonic final decay function is on. If the polyphonic final decay is not on, the contour generator integrating capacitor output is rapidly pulled toward ground via a diode connected to logic circuitry driven from the final decay circuit.

Each time a key is depressed, a filter contour is initiated. A sensing resistor is connected to each drive point of the polyphonic keyboard RC network and these resistors are commonly connected to a trigger amplifier which sums currents provided via the lowest level drive buss. A d-c trigger detector determines whether this total current exceeds a minimum value and if it does, the detector generates a d-c trigger signal. As successive keys are depressed on the keyboard, the trigger amplifier output voltage changes in steps and the a-c trigger detector generates a 5 msec pulse. Single or multiple triggering, selected by the TRIG MODE ON-OFF switch, is available at the S-TRIG OUT jack on the rear panel. In the multiple trigger mode, the contour generator will re-attack at the maximum level of the attack rate whenever successive keys are depressed. Note that the trigger signal is derived from the polyphonic keyboard system.

The monophonic keyboard system on the TR board is comprised of two resistor strings, one for the lower two octaves and one for the upper four octaves. Whenever a key is depressed, a tap at the appropriate point in the resistor string is connected to the monophonic keyboard buss. Either the lower or upper resistor string (but not both simultaneously) has a constant current source applied to generate a constant voltage interval between successive notes of approximately 0.5 volt.

The VCF KEYBOARD LOWER-UPPER audio select pushbutton switches also determine whether the lower or upper resistor string is active (connected to a current source). The two resistor strings are connected to a common current source device which employs diode isolation. When one resistor string is



active, the other string is floating between reverse biased diodes. This diode isolation is used to prevent loading of the upper resistor string by the lower resistor string if the VCF is in the upper mode and keys are depressed simultaneously on both the upper four octaves and lower two octaves. Loading could occur if isolation was not used because a common keyboard buss is used for all six octaves.

The upper keyboard resistor string has a fixed voltage applied to the top and a current sink applied to the bottom resulting in high note priority. When the lower keyboard resistor string is activated, a fixed voltage is applied to the bottom of the resistor string and a current source is applied to the top of the string resulting in a low note priority.

The monophonic and polyphonic keyboard contacts associated with each key are arranged so that the monophonic buss contact closes first. As mentioned previously, a 5 msec trigger derived from the polyphonic keyboard section drives a sample and hold circuit using a CD4016 CMOS switch. The voltage on the keyboard sample and hold capacitor is buffered by a high impedance follower, followed by a CA3080 integrated circuit used as a remote controlled current source, a second capacitor and a second buffer amplifier whose output is returned as the feedback reference to the initial buffer amplifier. The CA3080 integrated circuit current source is controlled by the front panel EXT KB GLIDE control.

The a-c trigger is used instead of the d-c trigger to acquire keyboard voltage so that new keyboard voltages are acquired only when a new key is depressed. This type of keyboard sampling, for example, prevents jump down of the monophonic keyboard signal as notes of a chord are released.

The monophonic keyboard voltage is applied to the external KB OUT connector via a CMOS isolation gate and also to the keyboard amount voltage controlled amplifier. The EXT SYN ON-OFF switch input controls the external KB OUT and S-TRIG OUT signals.

The keyboard amount VCA is comprised of a CA3080 integrated circuit used as a variable gain amplifier, whose output is applied to the input of the filter current source along with the output of the contour amount VCA, sample and hold amount VCA, external filter cutoff input and modulation amount VCA. All of these inputs are summed and applied to an NPN/PNP current source. The contour, modulation, and sample and hold amount VCAs all use CA3080 integrated circuits as current controlled variable gain amplifiers.

The modulation oscillator is identical to that described for the frequency modulation oscillators. The square wave output from the filter modulation oscillator is differentiated and applied to a sample and hold gate utilizing a CA3080 integrated circuit. This sample and hold gate samples the output of a filtered noise source and applies its output to the sample and hold amount VCA.

The direct OUTH, OUTM and OUTL outputs from the high, medium and low mother boards are summed and applied to the DIRECT master gain control on the front panel. The return direct signal is applied directly to the summing and drive amplifier, as are the VCF, (RESONATOR) and MODE (preset) outputs and the AUX input from the rear panel. In addition to driving the summing and drive amplifier, the DIRECT, VCF, RESONATOR and MODE (pre) signals are a-c coupled directly to rear panel output connectors. The summing and drive amplifier combines these signals and drives a 600-ohm balance line mix output connected to a BAL MIX (XLR) connector on the rear panel. The gain of this amplifier is determined by the SWELL input controlled by a LED photocell attenuator to provide remote loudness control.

The TC circuit board contains eight mode (preset) filters and three variable gain, cutoff frequency and Q state variable filters. Outputs from the modulator/generator mother boards pass through select gates which determine whether filters on the TC board are driven by the bottom two octaves or the top four octaves or all six octaves combined. Signals from the selected mother boards are applied to drive amplifiers which drive balance resistors to compensate for signal level differences of different presets. In addition, these drive amplifier signals are summed by another drive amplifier which in turn drives the resonators (Q state variable filters).

The balance resistors convert audio drive amplifier voltages to eight different scaled currents. The current level appropriate for a particular preset is routed through the preset gain select and eight-to-one analog switch multiplexer driven by the binary encoded preset number. The selected current is applied to a gain recovery amplifier which drives eight master preset fixed filters in parallel. The outputs of the eight fixed filters are applied to the inputs of a second

eight-to-one analog switch multiplexer driven again by the binary coded preset number. The output of this second selector is applied directly to the MODE master gain control on the front panel whose output is returned to the summing and drive amplifier on the TR board.

The output of the drive amplifier for the RESONATORS is applied to three (LOW, MED and HIGH) front panel RESONATOR GAIN controls. The outputs from these GAIN controls are returned to the TC board and applied to the inputs of three filters covering the frequency ranges of 50 to 300 Hz, 300 to 1500 Hz and 1500 to 7500 Hz. Each of these Q state variable filters has independent lowpass, bandpass and highpass outputs. The corresponding sections of each filter are summed together via isolation resistors and applied to an analog CMOS selector switch driven by the HIGH-LOW-BAND selector switch on the front panel. The output of this analog selector switch is applied to a drive amplifier supplying the master GAIN control for the RESONATOR section. The output from this GAIN control wiper arm is returned to the summing and drive amplifier on the TR board.

In summary, the Polymoog has five output channels: (1) DIRECT, unfiltered sum of three mother board outputs; (2) VCF, voltage controlled filter output; (3) RES, resonators output; (4) PRE, mode (preset) filter output; and (5) MIX, sum of (1) through (4) and the AUX input.

1.10 OSCILLATOR RANKS (Refer to Figure 1-4)

The oscillator ranks are physically located on the divider board assembly and consist of two independent frequency divider chains, one for the sawtooth rank and one for the rectangular rank and two high frequency oscillator plug-in boards, each providing the twelve top notes of each oscillator rank.

The two phase comparator outputs from the TL board are applied to the high frequency oscillator boards to drive lowpass filters, high frequency voltage controlled oscillators and drivers which in turn drive the top octave synthesizers. The top octave synthesizer outputs are applied to the frequency dividers and two outputs from each of the divider ranks are fed back to the high frequency oscillator boards for octave select. When the FOOTAGE controls for a particular oscillator rank are changed on the front panel, one of the divider return frequencies is selected via the octave select gates and returned to the phase comparator on the TL board. This phase comparator compares the returned frequency with the reference frequency from the precision low frequency on the TL board and provides a correction signal to the low-pass filter if the two frequencies do not match exactly. Thus, octave selection is accomplished by forcing the phase lock loop to compensate for a change in the selected return frequency. The outputs of the divider are applied directly to the modulator/generator mother boards via connectors.

1.11 POLYMOOG AND POLYMOOG KEYBOARD PRELIMINARY CHECK

Prior to disassembly, perform the following checks.

a. Make certain that the 110/220 VAC power selector switch on the left side of the rear panel is in the proper position before turning the instrument on.

b. Visually inspect power cord for possible damage.

c. Make certain instrument is connected and operated according to Owners Manual. If possible, check associated equipment such as cables, jacks, amplifier or audio monitor used with the unit for proper operation. Headphones may be plugged directly into the MIX (MAIN on Polymoog Keyboard) output connector to check the audio monitor.

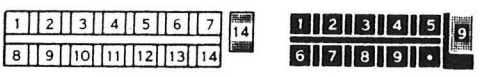
d. Ascertain +5 VDC power supply is operating by observing illumination of red indicator lights (LEDs) adjacent to pushbutton switches and the numeric display at the center of instrument.

e. Connect monitor system to MIX (MAIN on Polymoog Keyboard) output connector, select preset 1, raise DIRECT master gain control (Volume on Polymoog Keyboard) and depress key. If instrument is not operating properly at this point, proceed with disassembly.

1.12 DISASSEMBLY

a. Disconnect power cord connector and all other rear panel connections.

b. Remove four screws securing cover to rear panel extrusion using a medium sized Phillips head screwdriver.



c. Loosen two captive knurled thumb screws under the instrument extreme front left and right sides until they turn freely and lift cover directly up.

d. Reconnect power cable and audio signal monitor.

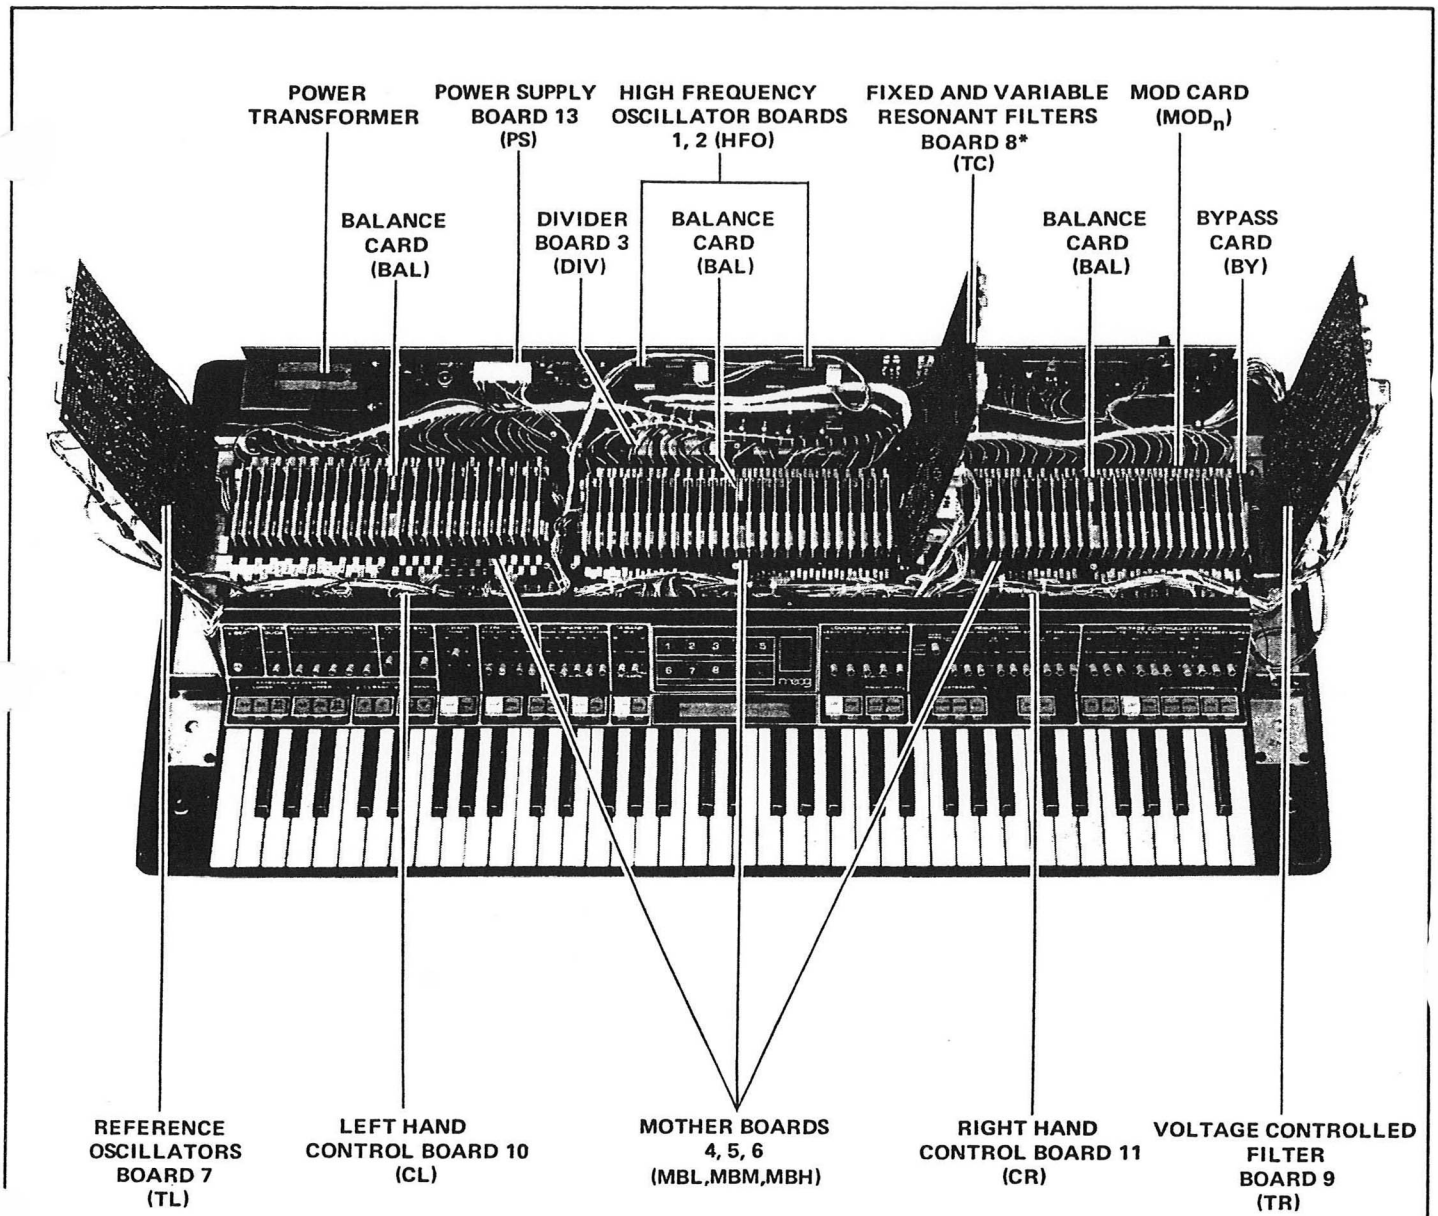
> **NOTE**
> All internal alignment and adjustment controls are now accessible. Refer to Table 1-1 for the location of all printed circuit board assemblies.

1.13 VISUAL INSPECTION

a. Inspect unit for broken wires, damaged or missing components and other obvious defects.

b. Check that all electrical connectors and printed circuit board assemblies are properly located as shown in Figures 1-5 and 1-6 and inserted into their respective connectors.

c. Examine wiring harness and connections to front panel for loose or poorly soldered terminations.



* BOARD 8 CONTAINS 8 FILTER BOARDS: BOARD 1 STRING FILTER, 2 PIANO FILTER, 3 ORGAN FILTER, 4 HARPSICHORD, 5 FUNK, 6 CLAVINET, 7 VIBES, 8 MODE FOR BRASS.

FIGURE 1-5 POLYMOOG PRINTED CIRCUIT BOARD LOCATION

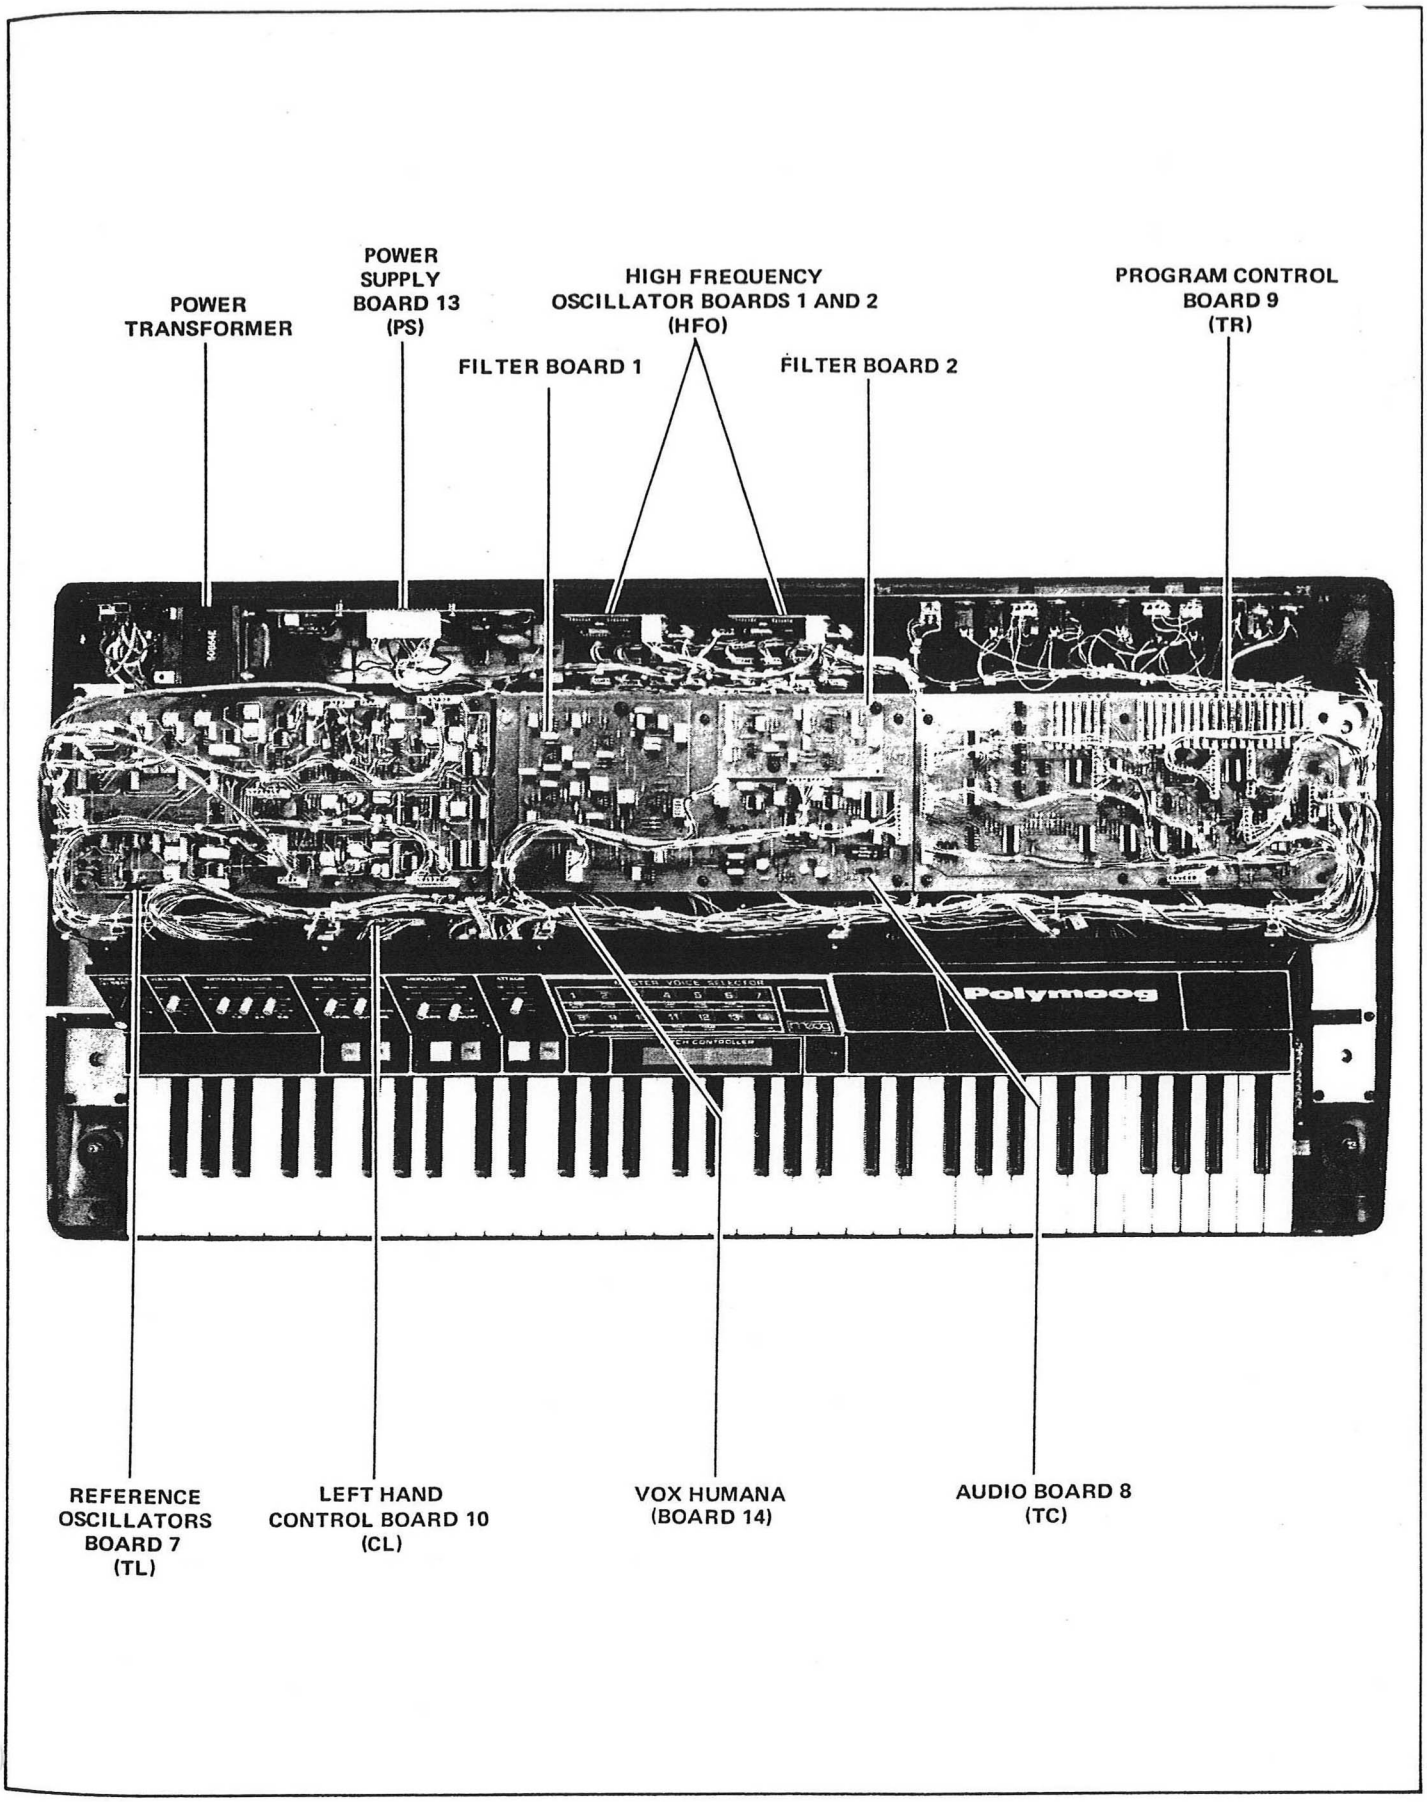


FIGURE 1-6 POLYMOOG KEYBOARD PRINTED CIRCUIT BOARD LOCATION

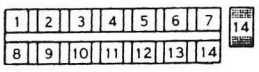

1.14 POLYMOOG AND POLYMOOG KEYBOARD TEST, TROUBLESHOOTING AND ADJUSTMENT

The basic approach to troubleshooting is to locate which printed circuit board or subassembly is malfunctioning. If a problem is located on a particular printed circuit board and corrected, it will not be necessary to adjust any internal controls, with the possible exception of the board on which the malfunction occurred. If necessary, the controls on each printed circuit board can be aligned separately.

1.15 TEST EQUIPMENT

The following electronic test equipment is recommended for complete servicing and alignment:

a. Digital voltmeter, minimum 3-1/2 digits with millivolt resolution.

b. Oscilloscope, minimum 5 mHz frequency response and 10 millivolt sensitivity.

c. AC voltmeter for audio frequencies, minimum 10 millivolt full scale sensitivity on low scale.

d. Audio oscillator, 20 to 20kHz frequency range.

1.16 TROUBLESHOOTING

In all cases of troubleshooting and alignment, the power supply assembly output voltages must be checked first and adjusted if necessary. Table 8-1 provides a procedure for determining whether the power supply itself is operating properly or, if a supply voltage cannot be obtained, locating the malfunctioning printed circuit board. The +15, -15 and +5 VDC outputs (see Figure 8-3) are set to their nominal values within 10 millivolts. The most common anticipated problem related to the power supply assembly is failure of the supply itself or shorts within the distribution network.

A shorted power supply voltage is usually caused by a defective semiconductor such as an integrated circuit, diode or transistor. Normally, this type of short results in the malfunctioning component getting hot, and if a short has been traced to a specific board, a defective component can be located by simply finger touching the components with power applied to the board.

In many cases, the printed circuit board or assembly location of a malfunction will be obvious from the nature of the problem. In Volume II the detailed block diagram will serve as a basic guide for determining the malfunctioning printed circuit board. For example, if the voltage controlled filter is working properly, but the filter modulation is not, then either the problem is in the front panel control assembly or on the TR board itself. Again, it should be emphasized that the primary goal at this point is to locate the board or subassembly which is malfunctioning. Tables 1-3 and 1-5 and Figures 1-7 and 1-8 correlate front panel controls and rear panel connectors with a printed circuit board or subassembly. When a malfunction is identified as associated with one of these controls, the most likely board location for the difficulty can usually be determined from this table and figure. Table 1-4 contains a list of possible malfunctions along with the most probable associated malfunctioning printed circuit board. Once the location of the difficulty has been associated with a particular board or subassembly, proceed to the troubleshooting section for that particular assembly.

NOTE

The Polymoog and Polymoog Keyboard have been designed with a large number of internal connectors provided primarily for serviceability. The system may be powered up with any of the boards disconnected without resultant damage.

	1 thru 8	SW1 thru SW8		Pushbuttons select one of eight basic preset operating modes (string, piano, organ, harpsicord, funk, clavinet, vibes or brass).
	9	SW9		Pushbutton places entire instrument into a variable mode.
		SW10		Lamp lit defeats canceling action (return to preselection state) when a mode 1 thru 8 pushbutton is depressed.
12	PITCH CONTROLLER	R62	TL,CR	Varies pitch of entire instrument plus or minus a musical sixth.
13	Digital Display	L1	PRE,CR	Displays basic preset operating mode selected by mode selector control panel pushbutton.
14	LOUDNESS CONTOUR			
	KB DYN (Black)	R47	TL,CR	Determines amount of dynamic keyboard effect.
	ATTACK (Black)	R53	TL,CR	Determines attack rate if sustain level is raised.
	LOWER KEYBOARD D/R (Black)	R51	TL,CR	Adjusts initial and final decay rates of lower two octaves to the sustain level.
	UPPER KEYBOARD D/R (Black)	R49	TL,CR	Adjusts initial and final decay rates of upper four octaves to the sustain level.
	SUSTAIN (Black)	R55	TL,CR	Determines sustain level while key is depressed.
	VAR - PRE	SW16,SW17	CR,TL	Pushbuttons select either variable or preset mode for loudness contour control. Illuminated LED identifies selection.
	FINAL DECAY LOCK - MAN	SW14,SW15	CR,TR	Depressing LOCK pushbutton selects final decay unconditionally ON, while depressing MAN pushbutton allows foot pedal control of final decay. Illuminated LED identifies selection.

TABLE 1-3

POLYMOOG OPERATING CONTROLS AND INDICATORS (Continued)

FIGURE 1-7 INDEX NO.	PANEL MARKING	REF DESIG	ASSOCIATED PRINTED CIRCUIT BOARD	FUNCTION
15	RESONATORS			
	PASS MODE LOW-BAND-HIGH	SW1	TC	Selects either low band or high pass mode for low, medium and high resonators simultaneously.
	LOW CF (Black)	R60	TC	Adjusts cutoff frequency of low resonator between 60 and 300Hz.
	LOW EMPH (Black)	R59	TC	Sets emphasis (Q) of low resonator.
	LOW GAIN (Red)	R58	TC	Determines gain of low resonator.
	MED CF (Black)	R70	TC	Adjusts cutoff frequency of medium resonator between 300 and 1500Hz.
	MED EMPH (Black)	R69	TC	Sets emphasis (Q) of medium resonator.
	MED GAIN (Red)	R68	TC	Determines gain of medium resonator.
	HIGH CF (Black)	R82	TC	Adjusts cutoff frequency of high resonator between 1.5 and 7.5KHz.
	HIGH EMPH (Black)	R81	TC	Sets emphasis (Q) of high resonator.
	HIGH GAIN (Red)	R80	TC	Determines gain of high resonator.
	KEYBOARD LOWER-UPPER-ALL	SW11, SW10, SW9	TC,CR	Selected pushbutton determines whether resonator inputs are applied from the lower two octaves, upper four octaves or all octaves. Illuminated LED identifies selection.
	ON-OFF	SW12,SW13	TC,CR	Pushbuttons select whether resonator audio channel is on or off. Illuminated LED identifies selection.
16	VOLTAGE CONTROLLED FILTER			
	CUTOFF (Black)	R9	TR,CR	Varies cutoff frequency of voltage controlled filter.

16 cont.	EMPH (Black)	R11	TR,CR	Sets emphasis (Q) of voltage controlled filter.
	KB (Black)	R42	TR,CR	Determines amount of monophonic keyboard buss voltage applied to voltage controlled filter.
	MODULATION RATE (Green)	R7	TR,CR	Sets frequency rate of voltage controlled filter modulation oscillator and sample and hold circuits.
	MODULATION AMT (Yellow)	R13	TR,CR	Determines amount of repetitive voltage voltage controlled filter modulation.
	MODULATION S & H (Black)	R5	TR,CR	Adjusts amount of sample and hold modulation of the cutoff frequency.
	CONTOUR AMT (Yellow)	R21	TR,CR	Sets amount of filter contour.
	CONTOUR ATTACK (Black)	R17	TR,CR	Determines attack rate of filter contour.
	CONTOUR DECAY (Black)	R19	TR,CR	Selects initial and final decay of filter contour.
	CONTOUR SUSTAIN (Black)	R15	TR,CR	Determines sustain level of filter contour while key is held.
	ON-OFF	SW3,SW4	TR,CR	Pushbuttons select whether voltage controlled filter audio channel is on or off. Illuminated LED identifies selection.
	VAR - PRE	SW16,SW17	CR,TR	Pushbuttons select either variable or preset mode for voltage controlled filter parameters. Illuminated LED identifies selection.
	KEYBOARD LOWER-UPPER	SW5,SW6	CR,TR	Pushbuttons determine whether monophonic keyboard voltage is derived from lower two octaves or upper four octaves. Illuminated LED identifies selection.
	KEYBOARD ALL-SPLIT	SW7,SW8	CR,TR	Pushbuttons determine if audio feed to voltage controlled filter is from entire keyboard or if it is determined by the KEYBOARD LOWER-UPPER pushbuttons. Illuminated LED identifies selection.

TABLE 1-3

POLYMOOG OPERATING CONTROLS AND INDICATORS (Continued)

FIGURE 1-7 INDEX NO.	PANEL MARKING	REF DESIG	ASSOCIATED PRINTED CIRCUIT BOARD	FUNCTION
17	Keyboard		KB	Provides 71 musical note responses for polyphonic or monophonic control of the instrument.
18	FOOTAGE			
	⩘ RANK 8′ - 4′	SW7,SW8	CL,TOS,TL	Pushbutton selects sawtooth rank oscillator frequency of 8′ or 4′. Illuminated LED identifies selection.
	⎍ RANK 16′ - 8′	SW9,SW10	CL,TOS,TL	Pushbutton selects sawtooth rank oscillator frequency of 16′ or 8′. Illuminated LED identifies selection.
19	KEYBOARD WAVESHAPE			
	LOWER	SW1,SW2, SW3	CL,TL	Pushbuttons select sawtooth, rectangular or both waveshapes for the lower two octaves. Illuminated LED identifies selection.
	UPPER	SW4,SW5, SW6	CL,TL	Pushbuttons select sawtooth, rectangular or both waveshapes for the upper four octaves. Illuminated LED identifies selection.
20	BEAT	L1	TL	Displays difference between reference high frequency oscillator beat rates.
21	S-TRIG OUT	P1	TR	Provides single or multiple trigger output determined by TRIG MODE selector switch (26).
22	KB OUT	J4	TR	Provides monphonic keyboard control voltage output for controlling an external synthesizer.
23	KB SCALE	R1	TR	Adjusts keyboard output voltage range.
24	MOD AMT	J17	TR	Input controls amount of frequency and pulse width modulation when appropriate front panel controls are in the VAR mode.
25	EXT SYN ON-OFF	J2	TR	Switch ON-OFF input controls outputs of S-TRIG OUT and KB OUT connectors (21 and 22).

TABLE 1-3

POLYMOOG OPERATING CONTROLS AND INDICATORS (Continued)

FIGURE 1-7 INDEX NO.	PANEL MARKING	REF DESIG	ASSOCIATED PRINTED CIRCUIT BOARD	FUNCTION
26	TRIG MODE ON-OFF	J13	TR	Switch ON-OFF input determines single or multiple trigger mode at S-TRIG OUT connector (21).
27	BAL MIX (Output)	S2	TR	Provides XLR balanced line 600-ohm output.
28	MIX (Output)	J10	TR	Supplies single ended mix output derived from BAL MIX connector (27); insertion of jack automatically unbalances BAL MIX output to provide single ended output.
29	PRE (Output) Serial No. 1 thru 1600 MODE (Output) Serial No. 1601 and Subsequent	J8	TC,TR	Provides internal fixed filter mode channel output.
30	AUX (Input)	J9	TR	Provides an input for an external audio signal controlled by AUX master gain control on front panel; output appears at MIX connector (28).
31	VCF (Input)	J15	TR	Presents an input directly to voltage controlled filter. Output appears at VCF and MIX output connectors (36 and 28).
32	ACCESSORIES 1 and 2	S3,S4	PS	Provides +15, -15 and +5 VDC outputs for accessories.
33	RES (Input)	J16	TC,TR	Provides direct input to resonators; output appears at RES and MIX output connectors (34 and 28).
34	RES (Output)	J14	TC,TR	Provides resonator channel output.
35	DIRECT (Output)	J7	TC,TR	Provides direct channel output.
36	VCF (Output)	J6	TR	Provides voltage controlled filter channel output.
37	GLIDE ON-OFF	J5	TR	Switch ON-OFF input activates front panel EXT KB GLIDE control (3).

TABLE 1-3

POLYMOOG OPERATING CONTROLS AND INDICATORS (Continued)

FIGURE 1-7 INDEX NO.	PANEL MARKING	REF DESIG	ASSOCIATED PRINTED CIRCUIT BOARD	FUNCTION
38	SUSTAIN ON-OFF	J1	TR	Switch ON-OFF input controls final decay when front panel FINAL DECAY MAN pushbutton is depressed.
39	PITCH	J12	TR	Input varies frequency of high frequency oscillators; jack tip controls both oscillators simultaneously, stereo ring controls frequency of rectangular rank separately.
40	FILTER	J3	TR	Input varies the voltage controlled filter cutoff frequency.
41	SWELL	J11	TR	Input controls output level at BAL MIX and MIX connectors (27 and 28).
42	S-TRIG IN	S1	TR	Provides S-trigger input connection for filter contour.

1.17 KEYBOARD GENERAL SERVICING

Cleaning of the Polymoog keyboard is accomplished using a warm soap and water solution as the use of organic solvents, such as alcohol, may damage the plastic keys. Occasional cleaning of the keyboard contacts may be necessary, especially if the instrument is used extensively in smokey or corrosive conditions. The keyboard contacts may be accessed by unscrewing and removing covers underneath the keyboard at the bottom of the case. Extreme caution must be taken when cleaning the keyboard contacts or damage to one of the delicate spring contacts may result. Use a Q-tip soaked in alcohol or a high quality contact cleaner to remove dirt from the keyboard busses, the long gold plated wires running the full length of the keyboard.

1.18 REMOVAL

The only time it is required to completely remove the Polymoog keyboard is when replacing the entire keyboard or repairing the printed circuit board. To replace a key, set the instrument on a table so that the front edge of the instrument overhangs by approximately eight inches. Remove ten screws under the instrument which fasten the keyboard using a Phillips head screwdriver. Carefully slide the keyboard toward the front of the instrument so that small screws holding the black and white keys to their metal channels are exposed at the rear of the keyboard and remove the screw of the key to be replaced. If a white key is being replaced, gently lift the back part of the plastic and slide the part toward the front. If a black key is being replaced, depress adjacent white keys and remove the black key following the above instructions while holding the white keys depressed.

If it is necessary to remove the entire keyboard, perform the first stage of the front panel disassembly folding back the front panel assembly in a nearly vertical position. Remove 12 six-pin connectors connecting the keyboard to the mother boards and unplug connectors attached to two cables terminating at the right and left of the keyboard. Remove keyboard from unit being careful not to poke fingers underneath the edge of the keyboard when lifting to avoid damaging contacts or dislodging small springs between the keys and keyboard frame which attach to the key lever bars. Refer to Tables 1-6 and 1-7 for keyboard and general mechanical replacement parts lists.

1.19 TROUBLESHOOTING

Troubleshoot the keyboard and harness assemblies using the wire charts, part location diagram and schematic diagram in Volume II.

1.20 POLYMOOG AND POLYMOOG KEYBOARD LEVELING PROCEDURE

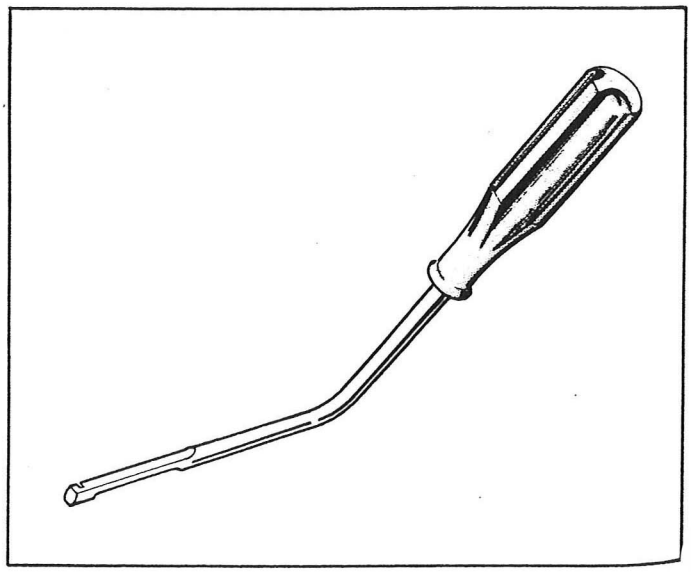
Key height on keyboard also determines contact sequence and wrap. Proper key height adjustment is important for proper keyboard triggering sequence playability. Use of hand leverage or long nose pliers, instead of the tool shown below may permanently damage keyboard mainframes.

a) Slide the keyboard forward after removing the ten screws on the case bottom.

b) Place the tool on the vertical member of the frame underneath the key requiring adjustment.

c) Downward motion moves the key height down.

> **NOTE**
> Refer to Volume II, Service Bulletin Section, for additional information.



KEY ADJUSTING TOOL

1.21 EXTERNAL SYNTHESIZER COUPLING

The external keyboard circuit in the Polymoog provides for coupling (controlling) a monophonic synthesizer such as the Micromoog, Minimoog, or Moog Modular systems from the Polymoog keyboard via rear panel connections (Figure 1-9). Control of other synthesizers is also possible provided keyboard control voltage and trigger compatability are provided.

The Polymoog keyboard circuit has both single and multiple trigger modes which may be controlled by a switch connected to a rear panel TRIG MODE jack. With no switch attached, the instrument is in the "multiple" trigger mode.

The Polymoog has a 71 note keyboard starting on E1. The external keyboard circuitry splits the keyboard in a 24 note (LOWER) section (ending on E♭2) and a 47 note section (UPPER) starting on E3 and ending on D6 (Figure 1-10).

The external keyboard circuit provides a control voltage (which may be scaled using the rear panel KB SCALE control) and a trigger. This control voltage (CV) is either the CV for the highest note of the UPPER keyboard or the lowest note of the LOWER keyboard as selected by the UPPER/LOWER push-button controls on the front panel of the Polymoog. The SPLIT/ALL selector must be in the SPLIT mode in order to activate the LOWER mode. Depressing the ALL mode forces the keyboard splitting function into the UPPER mode, with the keyboard CV derived from the UPPER keyboard but the rear panel trigger output will be derived from the ENTIRE keyboard. Refer to Table 1-8 for various keyboard modes and the associated control voltage and trigger characteristics.

The rear panel EXT SYN jack may be used to turn ON or OFF the control voltage (CV) and the trigger connected to the external keyboard control outputs. The CV and trigger outputs go to an open circuit condition when turned OFF.

1.22 CONTROL VOLTAGE ADJUSTMENTS

Two internal keyboard CV range adjustments set the precise output voltage for the lowest note of the UPPER keyboard signal (R103) and the highest note of the LOWER keyboard signal (R100). These

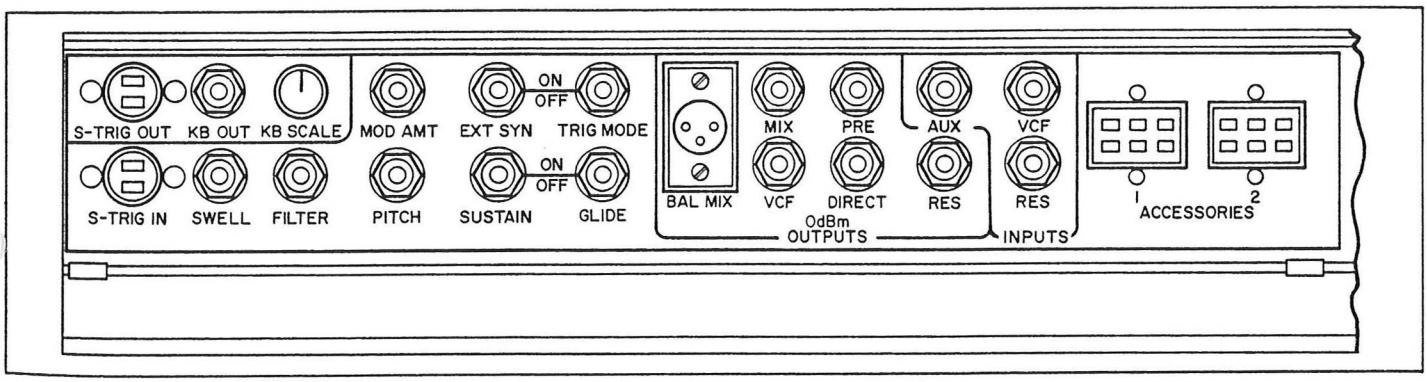

FIGURE 1-9 REAR PANEL

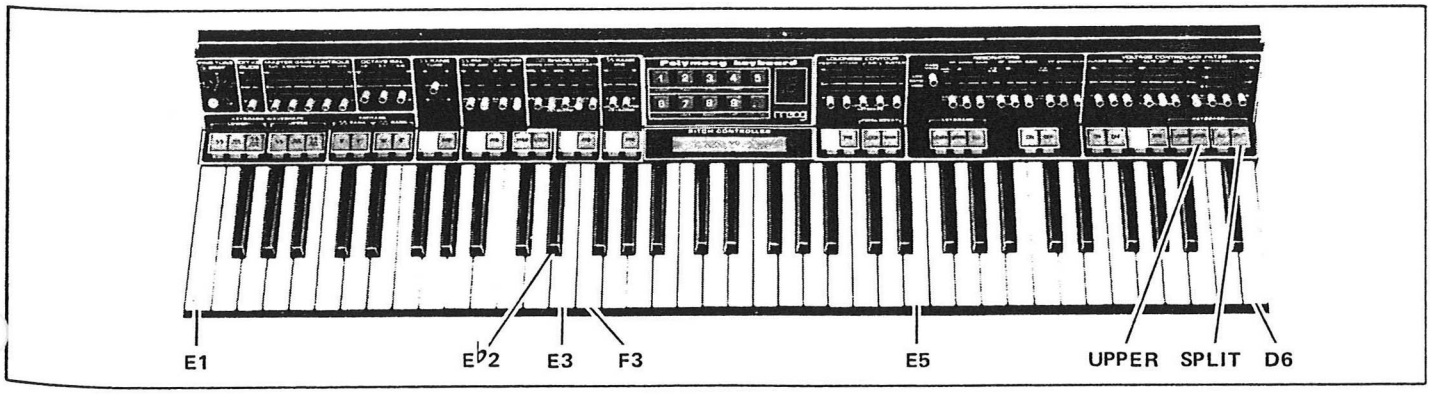

FIGURE 1-10 KEYBOARD

TABLE 1-8. POLYMOOG VARIOUS KEYBOARD MODES

UPPER/LOWER	SPLIT/ALL	CV/PRIORITY	TRIGGER
UPPER	SPLIT	UPPER-high note	From UPPER
LOWER	SPLIT	LOWER-low note	From LOWER
UPPER	ALL	UPPER-high note	From full keyboard

two trim pots are located on the top right (facing the instrument) printed circuit board (Figure 1-10) and may be used to adjust the reference voltage of the note E3 to zero ± 100 millivolts. Since the output CV is nominally 1.00 volt/octave (or 83.3 millivolts/semitone) the output CV may be adjusted so that E3 = 0.00 volts or so that E3 = 0.083 millivolts which establishes F3 = 0.00 volts when the rear panel KB SCALE pot is set for 1.00 volts/octave. In addition, there is an UPPER scale adjustment (R36) which is used to match precisely the keyboard UPPER and LOWER scale factors.

In general the internal trim RANGE controls are used to adjust for small but important pitch offsets when switching an externally controlled synthesizer ON and OFF using the EXT SYN jack. It is essential in this case that the external synthesizer stay precisely in tune BOTH when played independently and when coupled together. The following procedure describes the alignment procedure to be used when coupling a Micromoog I or II to the Polymoog.

1.23 CONTROL VOLTAGE ALIGNMENT

a. Remove the Polymoog cover and locate trim pots R100 and R103 (Figure 1-11).

b. Put the Polymoog into the SPLIT and UPPER modes using the front panel Polymoog switches. Use Polymoog PRESET 8 and Micromoog 16 pitch setting.

c. Tune the Polymoog and Micromoog to exact unison with the rear panel keyboard CV DISCONNECTED. Use the E3 key of the Polymoog and the lowest E of the Micromoog. Place the Micromoog external keyboard scale pot in the "click position".

d. Connect the Polymoog keyboard CV to the Micromoog keyboard OUTPUT; and while REPEATEDLY DEPRESSING E3 (Figure 1-10) on the Polymoog, adjust the keyboard HIGH RANGE trimpot R103 until both instruments are in tune.

e. Play the E5 note repeatedly (two octaves higher) on the Polymoog and adjust the rear panel KB SCALE pot for exact unison of the Polymoog and Micromoog.

f. Put the Polymoog in the LOWER mode, and while REPEATEDLY PLAYING E ♭ 2 (highest note of the lower keyboard section) adjust the keyboard LOW RANGE trim pot (R100) for exact Polymoog and Micromoog unison.

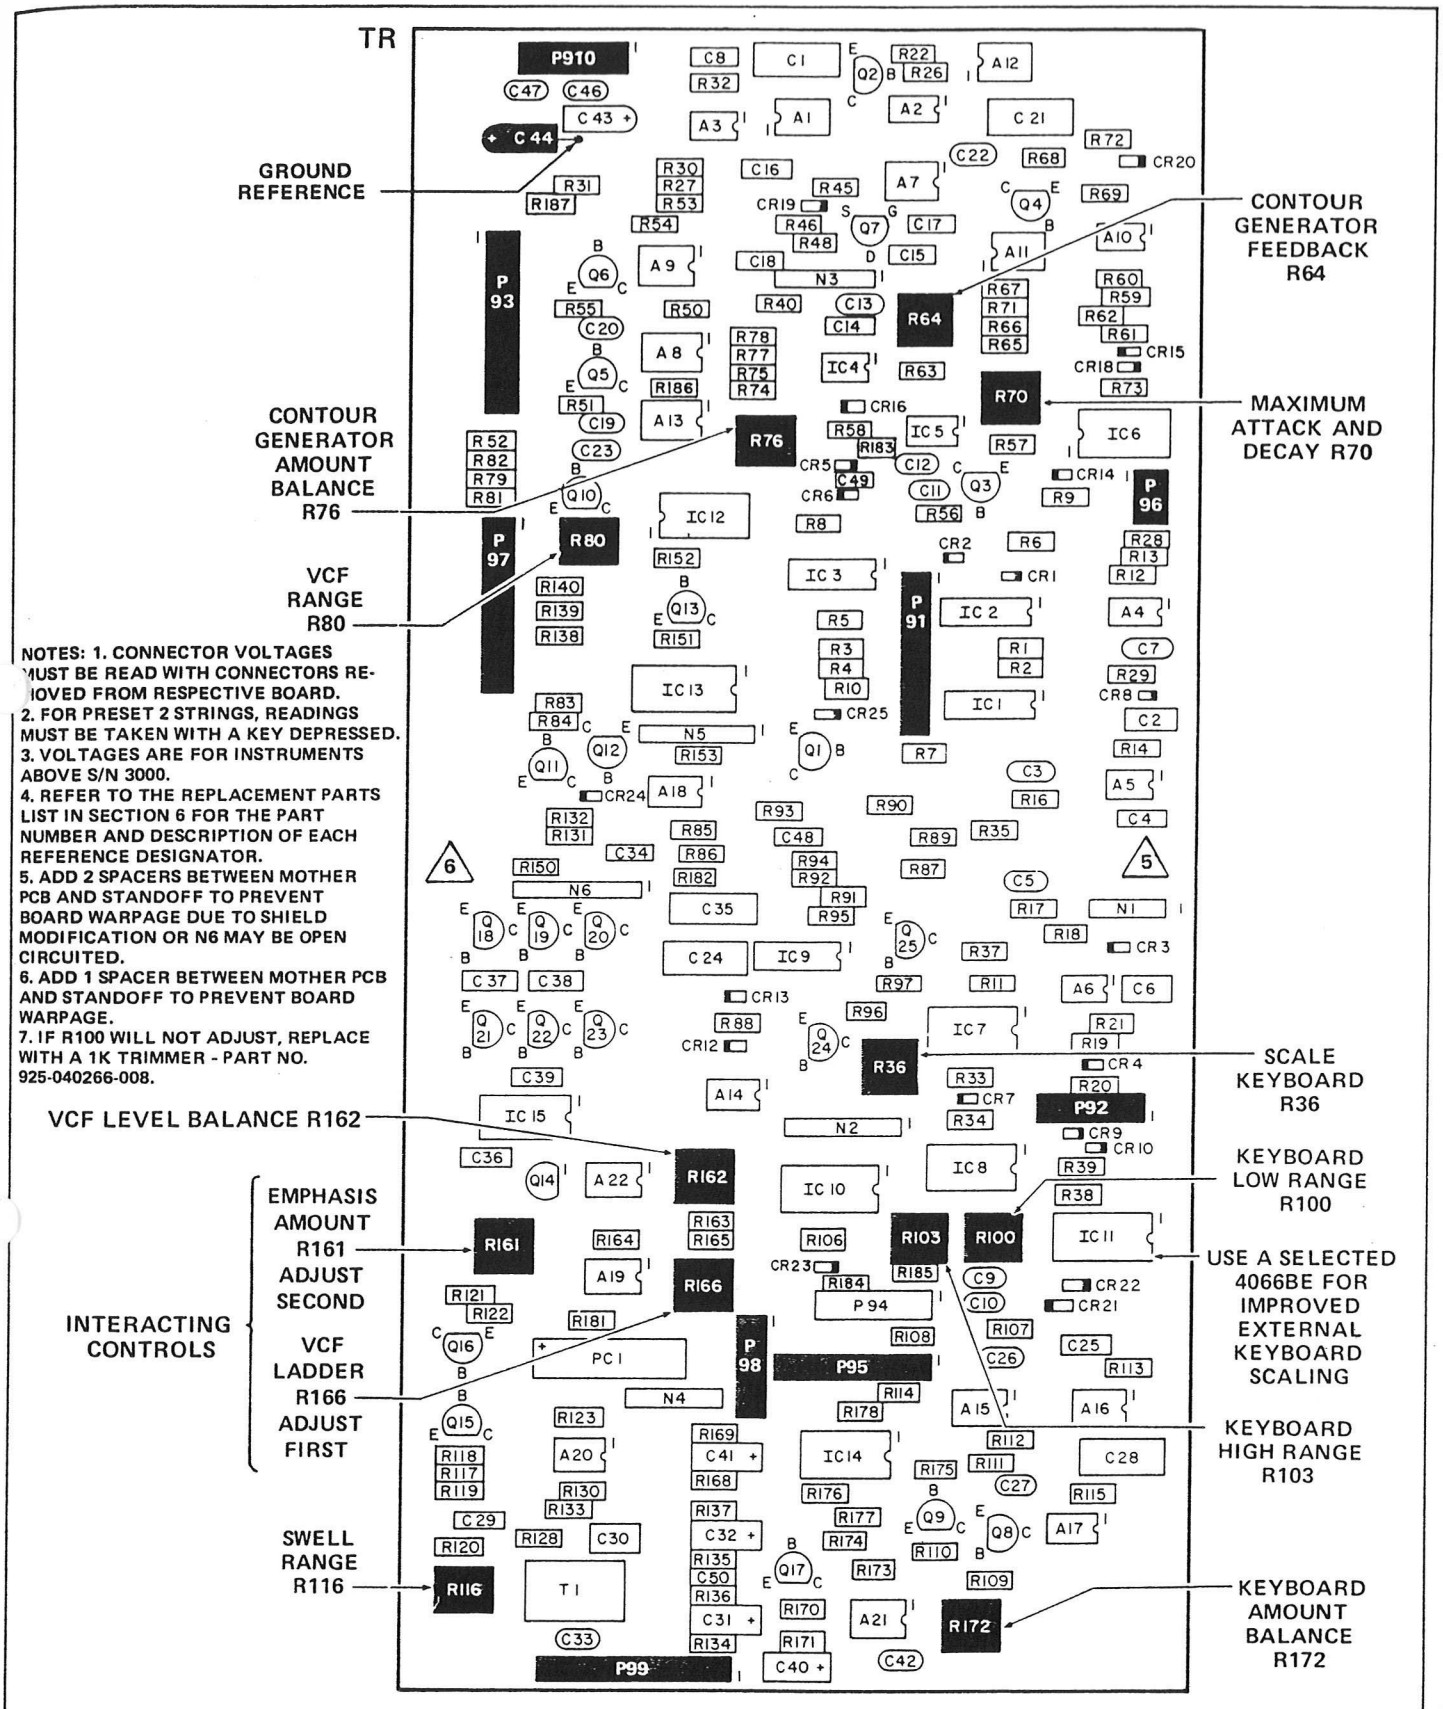
g. Check the LOWER scale by playing lower notes on the LOWER section of the keyboard.

Occasional small adjustment of the rear panel KB SCALE control should be the only adjustment required for setups after the above procedure has been completed. However, if a different Micromoog is substituted, the above procedure MAY have to be repeated.

The Polymoog keyboard output CV may also be connected to the Micromoog OSC input. However, the keyboard voltage of the Micromoog itself will then ADD to the injected CV. In this case the procedure is the same except that steps c thru e must be preceded by depressing the lowest note of the Micromoog to reset the (added) Micromoog CV to zero. This allows the player to use the Micromoog as a "transposing" keyboard, but with the disadvantage that a Micromoog note MUST be played occasionally to eliminate the inevitable long term drift of the keyboard sample and hold (MEMORY) circuit.

The use of the Minimoog is exactly the same as the use of the Micromoog OSC input as previously described.

A modification is available for the Minimoog which eliminates the keyboard control voltage but this modification requires mechanical pull-out of the CV plug at the Minimoog to return it to its own keyboard control.



Repeated on Inside Back Cover, Page 8-13, for Convenience While Performing Adjustments.

FIGURE 1-11 VOLTAGE CONTROLLED FILTER AND KEYBOARD PRINTED CIRCUIT BOARD ASSEMBLY (TOP RIGHT BOARD)

1.23.1 POLYMOOG KEYBOARD INTERFACING

The Polymoog Keyboard is interconnected with another instrument, for example, the Minimoog or Micromoog, in a manner similar to that described for the Polymoog Synthesizer. When interconnected, the second instrument will sound the highest key played on the Polymoog Keyboard. Interconnection and tuning is accomplished as follows:

a. Connect the S-TRIG output on the Polymoog Keyboard to the S-TRIG input on the second unit.

b. Connect KB OUT jack on the Polymoog Keyboard to the OSC INPUT on the Minimoog. On the Micromoog or Multimoog, plug into the KEYBOARD OUTPUT jack.

c. Set the second instrument to 8′ and play the lowest F on the Polymoog Keyboard.

d. Adjust the KB RANGE located on the rear panel of the Polymoog Keyboard while repeatedly striking the F key until both instruments are in unison.

e. Adjust the KB SCALE while repeatedly striking the highest note (D) until both units are in unison.

f. Should another unit be interconnected, the tuning process must be repeated due to individual instrument tolerances.

1.24 REAR PANEL CIRCUIT DESCRIPTION AND TROUBLESHOOTING

The controls subassembly provides all input/output connections to the main unit via 36 pin connector S02. The rear panel markings, locations, reference designators, connector pins, line labels and internal connector destinations are shown in Volume II.

The signal ground line (labeled ⧩) is returned to the TR board via pin 1 of P97 while the power or chassis ground is derived from the CR board via pin 2 of P111. These two separate ground lines are used to prevent clicks and pops when the external S-TRIG connections are used or when power is supplied to an external accessory via connector S3 or S4.

When a phone jack is plugged into MIX output connector J10, the output at the BAL MIX connector becomes unbalanced. Note that the VCF and RES inputs at connectors J15 and J16 are shorted to ground when no jack is inserted in order to eliminate clicks due to stray capacitive coupling between S-TRIG signals in the unit and input lines. Signal sources applied to these two inputs via J15 or J16 should have low internal source impedances of less than 10K ohms.

Troubleshoot the rear panel subassembly using the circuit description, (paragraph 8.1 or 8.2), part location and schematic diagrams (Volume II). If any particular input/output control function is completely inoperative, one possible cause is an open connection between the input/output connector and the printed circuit board destination of that function. The schematic may be used to directly track the origin or destination of a rear panel function by noting the connector designation at the bottom of the figure.

Example: P102-5 { Board 10 / Connector 2 / Pin 5

1.25 FRONT PANEL SUBASSEMBLIES

The front panel subassemblies consist of the right hand control and master preset (CR), mode selector control (MODE) and left hand control (CL) printed circuit board assemblies (Volume II).

1.26 GENERAL SERVICING POLYMOOG AND POLYMOOG KEYBOARD

The front panel control assembly is complex mechanically and electronically. Removal of the control boards involves a number of steps, therefore, it is recommended that careful determination of whether the problem lies in the front panel assembly should be made initially.

The circuit elements most likely to fail are the CMOS packs, LEDs and slide pots and it is possible to replace most of the CMOS packs without removing the control boards. It is necessary to disassemble the front panel section if a slide pot or LED must be replaced.

In general, there is a single CMOS 4007 associated with each front panel slide control function. If a malfunction associated with a particular front panel function occurs and appears to be related to the control signal provided by the front panel assembly, it is recommended that the related CMOS 4007 be

replaced. This is usually easier than a detailed circuit analysis of the problem. An error in a particular function of a single preset is probably associated with the programming resistor packs. These resistor packs are plugged into sockets and a programming error could be the result of an improper insertion of the resistor in the connector.

1.27 FRONT PANEL DISASSEMBLY

The procedure for disassembling the front panel assembly will be explained in three parts. The first stage allows access to the bottom of the control boards, the second stage disassembly allows access to the top of the control boards for replacement of parts that are trapped by the front panel extrusion and the third stage is a complete disassembly which is required to replace a slide control or remove the mode selector in the center of this panel.

It should be noted at this point that it is not necessary to disassemble the front panel assembly to replace a RIBBON PITCH CONTROLLER element.

The first stage of this disassembly proceeds as follows:

a. Remove two screws on the far left and two screws on the far right which pass through the black support bars attached to the front panel extrusion and screw into the side support brackets.

b. Remove sheet metal screws across the back of the control boards which screw directly into the instrument base.

> **NOTE**
> The entire front panel assembly may now be lifted up and folded back 180° above the keyboard in order to gain access to the bottom of the control boards.

The second stage of this disassembly is accomplished by rolling back the front panel assembly and removing the screws which hold the control boards to the front panel extrusion near the front and removing three screws which tie the control boards to the support brackets between the control boards and the front panel extrusion. The unit may be turned on and operated at this point. However, caution should be exercised to prevent shorts between the bottom of the control boards and the keyboard. This is accomplished by laying a strip of insulating material, i.e., cardboard, across the top of the keyboard to prevent shorting. This stage allows for LED replacement.

The third stage of disassembly is necessary only if it is required to replace a front panel slide pot or to remove the mode selector control board. This is accomplished by removing six screws which connect the top rear of the front panel extrusion to six brackets between the extrusion and the control boards. Once these screws have been removed, the front panel proper may be disconnected from the control boards by pulling the white connectors which plug into the control boards. Remove the slide pot subassembly as follows:

a. Remove all slide pot knobs using a small screwdriver to carefully pry off the knob pushing against the extrusion with the screwdriver.

b. Invert complete assembly and remove screws holding plastic tiewraps to the hex standoffs.

c. Remove the hex standoffs and nuts holding the slide pot assembly up against the front panel extrusion.

d. Remove slide pot by unsoldering wires and removing two small screws holding slide pot to subassembly plate.

1.28 RIBBON PITCH CONTROLLER REMOVAL

a. Remove the two outer screws which hold down the pitch controller base plate.

b. Lift entire pitch controller assembly up and out a short distance, enough to view the three wires attached and remove two inner screws holding the pitch controller element to the base plate.

c. Unsolder three wires from the pitch controller element noting carefully which wire is attached to its respective location.

1.29 TROUBLESHOOTING

Troubleshoot the front panel assemblies in accordance with instructions for Polymoog and Polymoog Keyboard contained in Section 7. Note that voltage levels and waveforms displayed on the schematic diagrams are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part.

It is possible that the failure of one of the CD4007 integrated circuits used as an analog switch

may fail in a manner that shorts the control line to all CD4007s in a section to either the negative or positive voltage rails. In this case, it will appear that all control functions in a particular section controlled by one VAR-PRE switch are defective simultaneously. For example, the VCF VAR-PRE switch control line for the right hand control panel (board 11) is labeled ZZ. If the ZZ line does not switch between +15 VDC and ground when the VAR-PRE switches are depressed, it could be the result of either a failure in control IC2 or any one of integrated circuits IC3 thru IC10.

Drive line generator IC2 should be replaced first. If the ZZ line still does not switch properly, then IC3, IC4, IC5, etc. should be sequentially removed while monitoring the ZZ line with an oscilloscope and switching back and forth between the VAR-PRE modes. Leave out the removed integrated circuits until the ZZ line operates properly. The defective pack is the one which prevents the ZZ line from switching.

Replacement of TIP29 and TIP30 power transistors for the 4.85V and -5.5V supplies requires drilling out the rivets with a No. 22 drill. For later instruments, removable screws and Tinnerman fasteners are used to mount the transistors. These parts may be used in older instruments for convenience once the old parts are removed.

1.30 POLYPEDAL

The Polymoog pedal accessory (Polypedal, Figure 1-12) provides six control functions to the Polymoog. Three of these control signals, namely the PITCH, FILTER and SWELL functions are continuous control signals ranging from zero to 5VDC. The other three functions, namely, the EXT, SYN, TRIG MODE and SUSTAIN are switch controls.

There are four functions on the Polymoog which may be controlled by the three continuous control signals: PITCH, MOD. AMT. and SWELL. It should be noted that the PITCH control signal from the Polypedal can be used only to source current, and that the MOD. AMT. input on the Polymoog requires sinking current. Thus, the PITCH output of the Polypedal cannot be used to drive the MOD. AMT. input on the Polymoog.

The Polypedal assembly receives +5VDC power via the six pin Jones connector P7. There are two ground lines in the Polypedal circuit. The first of these, the power ground, is connected to P7, pin 2. This power ground carries the LED indicator lamp currents and is separated from the signal ground so that the on and off switching of the LEDs will not cause voltage offsets at the Polypedal because of the finite ground wire resistance. The power ground is shown as an inverted triangle with the symbol "P" inside and the corresponding signal ground is shown as an inverted triangle with an "S" inside. The signal ground is connected to the Polymoog or Polymoog Keyboard via the SWELL OUTPUT phone jack body. The pitch/filter potentiometer R1 is connected between ground and the +5VDC rail. The center tap on R1 (controlled by the left most "gas" pedal) is connected to the FILTER OUTPUT via the FILTER switch SW2 and to the PITCH output via the diode

CR1 and the secondary dividing potentiometer R2, a pitch range control potentiometer mounted on the rear of the Polypedal assembly. The diode CR1 provides deadbanding of the pitch control output voltage so that when the control pedal is in the retarded position, the output of the PITCH control line is precisely 0.000 VDC. The pitch scale potentiometer R2 allows the player to set the maximum effect of the pitch filter drive pot R1 to the desired musical interval. The PITCH and FILTER switches SW1 and SW2 respectively, simultaneously connect the respective outputs to the drive point and also turn on the indicating LEDs L1 and L2 at the same time. The capacitor C1 eliminates potentiometer noise on the PITCH/FILTER output lines.

The SWELL control signal is derived directly from the wiper of the SWELL potentiometer driven by the right most "gas" pedal. Potentiometer bypassing for this control signal occurs in the Polymoog itself.

The TRIG MODE and SUSTAIN controls are momentary foot switches which short the respective control lines to ground. The TRIG MODE switch has a reversing switch SW4 on the rear of the Polypedal which reverses the action of the foot pedal.

1.31 POLYPEDAL DISASSEMBLY PROCEDURE (Refer to Volume II for Illustrated Parts List)

The Polypedal can be serviced without complete disassembly for the majority of troubleshooting and adjustment procedures. Disassembly is performed as follows:

1.31.1 REAR COVER REMOVAL

Remove the four screws securing the rear cover. The following operation can be performed without further disassembly:

a.Cleaning switch contacts at the switch pedals.

b. Troubleshooting can be performed on the push switches, internal wiring and the components on the terminal strips. LED replacement can also be accomplished.

1.31.2 CONTROL PEDALS ADJUSTMENT

a. Pinion gear adjustment by use of a right angle drive Phillips screw driver.

b. Friction washer adjustment using right angle drive flat screw driver.

> **NOTE**
> The pedal has separate power and signal grounds. When troubleshooting the pedal separately from the Polymoog, the signal ground connected to the sleeve of the swell plug is independent of power ground (P7, pin 2). Place a jumper from signal to power ground when measuring output of control pedals.

1.31.3 CONTROL PEDALS REMOVAL

a. Remove the four screws and cup washers from the control pedal and lift out the pedal assembly.

> **CAUTION**
> Use care to avoid stress on solder connectors to the rotary pot.

b. Turn pedal end to end to gain access to pinion adjustment screw on friction washer adjustment bolt.

c. Adjust rack and pinion by loosening the 8-32 screw on the pot side of the bracket. The spool and spacer assembly will slide back in slot to disengage pinion.

1.31.4 SWITCH PEDALS REMOVAL

a. SUSTAIN and TRIG MODE switches are subassembled to a wood spacer. Remove the four screws and slide both switch assemblies out the rear opening in the vacuum formed enclosure. Remove pedals from spacer by loosening the two screws.

b. Leaf switches can be removed without further disassembly by removing the two screws.

c. The selflocking nut, which retains the pedal up-stop washer, can be adjusted slightly loose to correct rubbing of spacer against rubber grommet.

1.31.5 ACCESS TO THE VACUUM FORMED ENCLOSURE

a. Remove four screws.

b. Remove pedal subassemblies and slide enclosure to rear to clear front aluminum extrusion.

c. Push switches and LEDs are each subassembled to the metal bracket. Remove knurled nut and washer from each switch and the two screws from each metal bracket.

d. Remove the hexagon nut and lock washer securing the switch to the panel and remove switch.

NOTE

Hexagon nut and washer are used to provide clearance for the LED.

e. Rear panel components are subassembled to the rear panel. To remove the panel, remove the control knobs and screws and remove subassembly.

NOTE

Pitch trim pot is mounted to the rear panel using a special nylon friction locking nut. When installing, rotate nut on pot shaft to ease assembly.

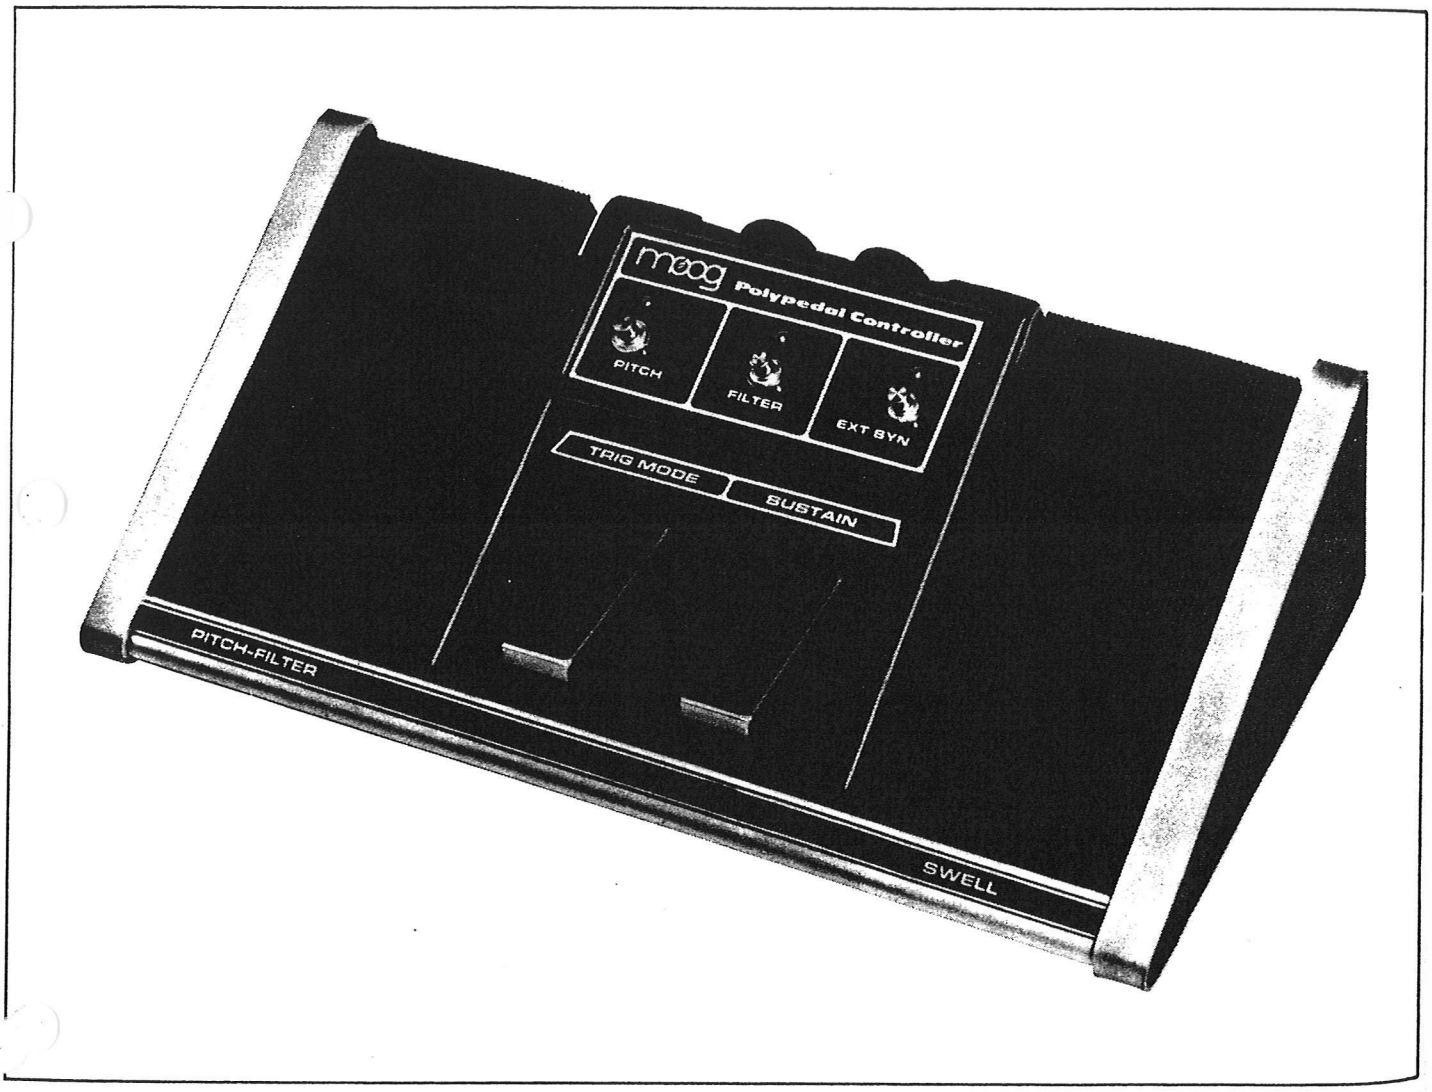

FIGURE 1-12 POLYPEDAL

SECTION 2
BOARDS 1, 2, 3
DIVIDER AND HIGH FREQUENCY OSCILLATORS

2.1 CIRCUIT DESCRIPTION

The divider and high frequency oscillator are used in both the Polymoog and Polymoog Keyboard. The circuit description that follows was developed primarily for the Polymoog and applies in general to the Polymoog Keyboard.

The divider printed circuit board assembly (board 3) carries 24 six stage PMOS frequency dividers and two 20-pin connectors for high frequency oscillator printed circuit boards 1 and 2. (Refer to Volume II).

Each high frequency oscillator board provides a full set of 71 audio tone sources to the modulator boards on each mother board. The rank 1 divider set provides drive for the sawtooth waveforms. The lines from the divider board to the modulator boards are labeled G_n where n is the note number, 1 being the lowest note on the keyboard. Power enters the board on 4-pin connector P325 and the +5.0 VDC supply is routed directly to the high frequency oscillator boards. The divider chips are powered by +15 VDC, ground and -15 VDC. The high frequency oscillator board provides the top twelve notes of the scale directly to the connectors and a 13th note one octave below the highest note of the original 12.

Each high frequency oscillator board is comprised of five sections: (1) a high frequency oscillator; (2) two-stage frequency divider; (3) octave selection gates plus a driver; (4) top octave synthesizer integrated circuit; and (5) selection gates for the return frequency to the phase comparators on the top left board.

The high frequency oscillator is comprised of Q1, IC1 (G1 and G2), IC4 (G3) and associated components. The output from the phase comparator on the top left board enters at pin 5 of P11/21 and is applied to a shelving filter comprised of R1, C1, R2 and C2. The phase comparator output is a switched signal filtered by this shelving filter and buffered by Darlington transistor Q1 which provides current to integrating capacitor C3 of the VCO via R3. Gates G1 and G2 are Schmitt triggers with upper and lower thresholds of approximately 0.8 and 1.7 VDC. When voltage across C3 reaches the upper trigger threshold of G1, the output of G1 goes negative causing the output of G2 to go positive causing the open collector output of G3 to shunt the voltage across C3 to ground. This action causes the polarity of gates G1, G2 and G3 to reverse and the voltage again begins to rise across capacitor C3. The oscillator output on pin 6 of IC1 is a 100 nsec pulse driving frequency divider G4 which drives a second frequency divider, G5. The first frequency divider, G4, is used merely to provide a square wave output while the second frequency divider provides an octave selection signal. The nominal range of the VCO comprised of Q1, IC1 and G3 of IC4 is 2 to 4 MHz.

Octave selection is achieved by selecting either the divided by 2 or divided by 4 high frequency signals using gates G6 and G7 (IC4) which are open collector output AND gates. Either G6 or G7 is enabled by a logic 1 on pin 1 or 3 of P11/21. The selected 15 volt square wave on pins 3 and 6 of IC4 is buffered by the complementary emitter follower driver comprised of Q2 and Q3. Resistor R8 is a protection resistor in case either Q2 or Q3 should fail. The 15 volt drive signal is applied to pin 2 of the top octave synthesizer (TOS), IC5. This IC generates the top 12 notes of the scale and in addition, a 13th output one octave below the highest of the twelve. These 13 tone source frequencies are applied to the divider board via edge connectors S1 and S2. These tone source frequencies are divided down on the divider board and applied to the modulator boards. In addition, a pair of outputs separated in frequency by one octave from the divider board are returned via pins 11 and 12 to the high frequency oscillator board when the drive frequency to the TOS is changed by an octave via control on pins 1 and 3 and gates G6 and G7 (IC4). Simultaneously, selection of one of two divided down and octavely related signals is returned to the high frequency oscillator board via G8 and IC3.

When the octave selection lines on pins 1 and 3 of P11/21 select the high frequency from divider G4 via G7, the lower frequency is selected to be returned to the phase comparators on the TL board via G* and IC3. Thus, when a rank is switched an octave higher the dividers are driven at twice their original frequency, but a return signal of half the frequency is sent back to the phase lock loop. The result is that the return frequency to the phase lock loop stays the same. Indeed the phase lock loop on the TL board is unaware that an octave shift has taken place except for a phase glitch.

2.2 GENERAL SERVICING

Malfunction of the divider packs on the divider board is easily determined by noting the absence of a 15 Hz audio waveform on the G connectors at the edge of each mother board. If no waveform is present at the edge of the mother board, record which note number in sequence of the keyboard is defective (note 1 is the lowest note) and determine whether it is a sawtooth rank or rectangular rank pulse. If it is a sawtooth rank, the inoperative pack can be located by noting which divider pack carries the appropriate key number designation. A similar procedure holds for the rectangular rank where the defective pack can be located by noting which pack carries the designator N_n being the note number mentioned previously.

The overall tone source system is comprised of three parts: (1) the reference oscillators on the TL board; (2) the high frequency oscillator which contains the top octave synthesizer; and (3) the frequency divider section. Malfunction of any one of these three sections can cause tone source problems since all three sections are in a feedback loop controlled by the phase lock circuitry on the TL board. Exchanging the high frequency oscillator boards will usually determine whether the difficulty lies with the high frequency oscillator board or the associated divider board section. If several notes in an octavely related note series for one of the oscillator ranks is completely dead, the TOS (IC5) or the first divider pack connected to the TOS is most likely at fault.

If there is hash or jitter in one of the oscillator ranks systems, determination of whether this fault is caused by the phase-lock loop or the high frequency oscillator may be made by jumping the base of Q1 to Vcc (+5 VDC). The phase lock loop circuitry is now defeated and the high frequency oscillator will run at a constant frequency, eliminating all jitter. Examination of the high frequency oscillator output at pin 1 of IC2, the driver output applied to pin 2 of the TOS (IC5) and the outputs of the TOS will determine whether the difficulty is in the high frequency oscillator, divider, driver or TOS.

> **NOTE**
> The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting procedures and after replacement of all malfunctioning parts.

2.3 REMOVAL

a. Remove 24 six-pin connectors from the divider board, two 5-pin connectors from the high frequency oscillator boards and carefully pull the high frequency oscillator boards from their edge connectors on the divider board.

b. Remove the six Phillips head screws from the divider board and lift divider board from unit.

> **CAUTION**
> When reinstalling divider board, use extreme caution when attaching the power supply connector to insure that it is properly polarized (note polarizing pin on connector).

2.4 TROUBLESHOOTING

Troubleshoot the divider and high frequency oscillator boards using Table 2-1, the circuit description (paragraph 2.1), part location and schematic diagrams (Volume II). Note that voltage levels and waveforms displayed on the schematic diagram are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part.

TABLE 2-1
POLYMOOG AND POLYMOOG KEYBOARD DIVIDER AND HIGH FREQUENCY OSCILLATOR BOARD TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
High frequency oscillator dead	Q1, IC1, IC4
High frequency oscillator runs, no drive to pin 2 of IC5	IC2, IC4, Q2, Q3
Drive signal to pin 2 of TOS (IC5), no TOS output	IC5
Octave switching malfunction	IC3, IC4, IC2
One tone frequency dead	Related divider pack on divider board
High frequency oscillator stays at maximum frequency	IC3

SECTION 3
BOARDS 4, 5, 6
MOTHER BOARDS, MODULATOR AND BALANCE BOARDS

3.1 CIRCUIT DESCRIPTION

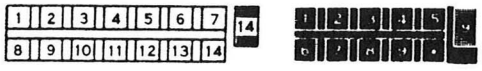
Circuitry for the low, medium and high mother boards is identical except for capacitor values. Each mother board contains 25 20-pin connectors, 24 of these connectors are for identical modulator boards while the center connector is for the balance board. (Refer to Volume II for schematics).

The 20-pin connectors are labeled S1 thru S25, respectively and the following pin references refer to these connectors. Tone frequencies are injected at the rear of the mother board on single pin connectors. Two frequencies per modulator board are applied to pins 17, 18 and 20 via capacitors. The two tone sources are 15 volt peak-to-peak square waves derived from the divider board. The keyboard drive signal is applied to pin 1 and power supply voltages of -5.5 and +4.85 VDC are applied to pins 9 and 8, respectively. Drive level limit control is applied to pin 11, final decay (with sustain) to pin 12, pulse width control to pin 13, sawtooth level control to pin 15, decay control to pin 16 and brightness control to pin 10. Pin 14 is the balance control to pin 10. Pin 14 is the balance control line driven by the balance board plugged into connector S13. Brightness filter capacitors connected to pins 2/3 and 4/5 are connected to the internal voltage controlled filter on each modulator board integrated circuit. Pins 1 and 2 of the balance board (S13) are connected to +15 and -15 VDC respectively and pins 6 and 7 are the differential current outputs of the modulator boards. These currents are summed simply by bussing them together and are converted to a single output voltage via amplifiers A1A and A1B and associated resistors. Capacitor C154 provides for RF interference suppression. The minus voltage supply to these amplifiers is bypassed by R5 and C153 to eliminate high frequency hash from entering the amplifiers on the minus voltage rail.

Referring to the modulator board schematic (Volume II), a composite d-c and 20kHz carrier signal is applied to pin 9 of the Polycom IC via C1 and to pin 10, the final decay control via R1 and CR1 when a key is depressed. Capacitor C2 is the contour capacitor which carries a voltage buffered internally and subsequently used to drive internal VCAs. The d-c step applied to pins 1 and 9 of the Polycom IC causes a step voltage to appear across contour capacitor C2. In addition, a-c voltage on the buss applied to pin 1 when a key is depressed causes a d-c voltage to also appear across contour capacitor C2. The applied composite keyboard signal operates in a manner described for the top left circuit board No. 7 (Section 4). Initial decay from the level appearing across the contour capacitor as a result of a d-c kick to the sustain level, determined by the amplitude of the a-c signal, will occur if current is injected on pin 10 of the Polycom IC either via key depression (through R1 and CR1) or via the foot sustain line on connector pin 12 and applied to pin 10 of the Polycom IC being held at ground potential.

The amount of brightness contour occuring via the transistor ladder contained in the Polycom IC connected via pins 1 thru 4 to capacitors on the mother board is determined by the voltage applied to pin 10 of the connector and thereby to pins 1 and 2 of the Polycom IC. The filter brightness voltage ranges between +1 and -10 VDC. When this voltage is -10 VDC, current is drawn down through the transistor ladder opening the filter and eliminating most of the filter brightness variation as the contour level changes. When filter brightness voltage is at 1 VDC, the filter opens in synchrony with the contour voltage appearing at contour capacitor C2. Pins 5 and 6 of the Polycom IC are open collector outputs and are bussed together for various modulator boards and applied to the differentiating amplifiers on the mother board. Pins 8 and 9 are the power supply busses to the Polycom IC.

The audio frequency drives applied to capacitors at the rear of the mother boards are differentiated by three capacitors and resistors on the modulator boards. For example, the audio drive coupled to pin 17 via a capacitor is differentiated by this capacitor and R10. The decay control of the contour is accomplished via a variable voltage applied to pin 16 of the connector and transmitted to the differentiated current via R9. In a similar manner, the capacitively



coupled signal at pin 20 is biased by the voltage input on connector pin 13 to accomplish pulse width control.

Repeated depressions of a key with foot sustain applied can cause buildup of the contour voltage on C2 to unacceptably high levels. To prevent this, a limit voltage is applied to pin 11 of the connector setting an upper bound for the voltage developed on C2 via clamping diode CR2.

Sawtooth level control is implemented by a voltage applied to pin 15 of the connector which provides a current to pin 14 of the Polycom IC and to the capacitor on the mother board connected to pin 19 of the edge connector. Circuitry in the Polycom IC causes a sawtooth voltage to appear on pin 14 the IC.

The Polycom IC contains two modulator sections. In order to achieve balanced modulation under a variety of sawtooth level and pulse width conditions, a voltage derived from the balance board is supplied to pin 14, a balanced input which injects a control current to the Polycom IC via R7.

The balance board contains a Polycom IC driven from the common bussed sawtooth level and pulse width control lines for all modulator boards. In addition, a constant "key" drive is applied to pin 9 the IC. The outputs at pins 5 and 6 of the Polycom IC on the balance board are differentiated, integrated and checked for balance. Any imbalance is amplified and applied to the balance input. Thus the balance board examines itself for imbalance and corrects it in a feedback manner. Since the sawtooth and pulse width controls for the balance board and the 24 modulator boards are identical, the balance board corrects for balance in all modulator boards at the same time it is correcting for its own imbalance.

Referring to the balance board schematic (Volume II), the output voltage at pin 1 of A1A is an audio frequency waveform referenced to 10.0 VDC portional to the difference of the current flowing rom output pins 5 and 6 of the Polycom in IC1. The d-c reference for this output is 10.0 VDC determined by the divider network comprised of R1 and R2. A 10.0 VDC bias voltage is also applied to integrator amplifiers A2A and A2B via divider network R6 and R7. If the output from the Polycom IC has a d-c imbalance, the d-c voltage on pin 1 of A1A will differ from 10.0 VDC.

This output voltage is applied to a fast integrator comprised of R4, R5, A2A and C1 and a slow integrator comprised of R8, C3 and A2B. When the imbalance of the Polycom in IC1 is large (for example, the result of changing waveshapes on the front panel control), the output on pin 1 of A2A deviates substantially enough from 10.0 VDC to forward bias either CR1 or CR2 driving the slow integrator via R10 at a rate 10 times faster than it can be driven via R8, the slow integration path. As the Polycom moves toward balance, diodes CR1 and CR2 no longer conduct and the only integration path is via R8. This integration waveshape has a long time constant (5 seconds) and the output of the integrator is returned to the balance input (IC1 pin 15) of the balance board Polycom IC through R9 and simultaneously applied to the common balance line (pin 14 of the modulator connector).

This combination of fast and slow integrators is used so that compensation circuitry may move rapidly toward balance when the waveforms are switched on the front panel via the fast integrator, but will contain very little residual ac because of the slow integrator time constant after having approached nearly perfect balance. Any residual ac on the output of A2B would couple into all of the modulator boards and cause output hash at the balance drive frequency, which is the same frequency as that applied to the 13th modulator board plugged into S14.

3.2 GENERAL SERVICING

Any malfunction associated with a particular modulator board may be isolated by exchange. For example, if a particular note appears to leak through with no note depressed, the associated modulator board can be quickly located and unplugged. If the leakage stops when the board is pulled and another board plugged into the bad location, then the fault is obviously on the modulator board itself. Malfunction of the balance board is indicated by "thumps" in the output when a key is depressed. Again this difficulty can be isolated by substituting a balance board from one of the other mother boards.

If a fault appears as the result of a defect on the mother boards, the top of the board should be examined for loose wires or damaged connectors before removal.

NOTE

The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting procedures and after replacement of all malfunctioning parts.

3.3 REMOVAL

a. Demount the top board above the mother board by removing the four hold-down screws and two nuts attached to the hinges.

b. Remove the six hex standoffs securing the mother board and disconnect the four 6-pin keyboard connectors at the front of the mother board.

c. Remove the control and power line connectors at the ends of the board.

NOTE

If the mother board does not have to be entirely removed from the unit, the rear audio input connector on the divider board can be left connected. This is usually the case if the only difficulty is a bad capacitor. Do not remove the push-on connectors on the rear of the board.

d. Roll back the board for inspection of the bottom side.

e. If it is necessary to completely remove this board, disconnect it by using the connectors at the divider board.

3.4 TROUBLESHOOTING

Troubleshoot the mother modulator and balance boards using Table 3-1, the circuit description (paragraph 3.1) and part location and schematic diagrams in Volume II. Note that voltage levels and waveforms displayed on the schematic diagram are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part.

TABLE 3-1
MOTHER BOARD TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
* No decay/ constant sustain on percussive presets on one note	Faulty capacitor attached to pin 17
* Thumps on the output for all notes associated with a mother board	Balance board (S13)
Noisy mother board output	A1, N1, modulator board (remove sequentially to locate the faulty board)
Dead note	Modulator card or open connection to pin 1 of edge connector
Shorted supply, -5.5 or +4.85 VDC	Shorted trace on mother board, shorted Polycom IC (remove sequentially to locate faulty board)
* Unusually bright or fuzzy waveform on output of one note	Bad filter capacitor attached to pins 3/3 or pins 4/5 of edge connector
No sawtooth waveform on one note	Faulty capacitor connected to pin 18 or 19

* These problems may also be caused by poor contact between the modulator card and connector. Clean modulator card connector contacts.

TABLE 3-1
MOTHER BOARD TROUBLESHOOTING (Continued)

PROBLEM	PROBABLE DEFECTIVE COMPONENT
No rectangular sawtooth output	Faulty capacitor connected to pin 20
Note too loud or too soft	Replace modulator card or adjust according to schematic information on modulator cards (Volume II)
* Note bleeds through constantly	Replace modulator card

* These problems may also be caused by poor contact between the modulator card and connector. Clean modulator card connector contacts.

SECTION 4
BOARD 7
REFERENCE AND MODULATION OSCILLATOR, WAVESHAPE AND KEYBOARD CONTROL
TL

4.1 CIRCUIT DESCRIPTION

The reference and modulation oscillator waveshape and keyboard control printed circuit board assembly (TL) contains the following major sections: (1) three modulation oscillators with associated voltage control amplifiers; (2) precision voltage controlled oscillators (VCO) with associated phase lock circuitry; (3) drive level limit control; (4) sawtooth level control; (5) decay control; (6) pulse width control; and (7) polyphonic keyboard buss control. (Refer to Volume II for schematic diagrams.)

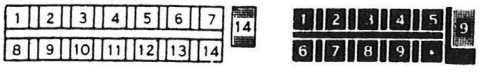
The three modulation oscillators are used to modify the pulse width and frequencies of reference oscillators No. 1 and 2. The pulse width modulation oscillator is comprised of A1A, Q1, A2, A3B, A3A and associated components. The rate of this modulation oscillator is controlled by current injected on the PWMRN line causing the output of A1A to go negative translating the input current to the bias input terminal of the CA3080E, pin 5 of A2.

Amplifier A1A is used to provide a zero potential summing node for currents injected on the PWMRN line and, as mentioned, translates this current via the high impedance output at the collector of Q1. The CA3080E, A2, is used as a current switch, whereby current flowing into the bias input terminal (pin 5) appears at the output (pin 6) in either positive or negative polarity determined by drive polarity on pin 3, the positive input of A2. The current output of A2 causes a linear ramp voltage on capacitor C1 whose voltage is buffered by amplifier A3B and applied to the negative input of a Schmitt trigger comprised of A3A, R9 and R10. Positive feedback from the output of A3A occurs via divider R9 and R10 to the positive input (pin 3) of A3A. The output on pin 1 of A3A swings from approximately +14 to -14 volts and applies approximately ±2.5 VDC to the positive input of both A3A and current switch A2. At the time the output of A3A swings to one limit, the current direction on the output of A2 is reversed and the linear voltage ramp on C1 is thereby reversed. This action results in a triangular wave appearing on the output of A3B.

Operation of reference oscillators No. 1 and 2, comprised of A1B, Q2, A4, A5B and A5A and A6A, Q3, A7, A8B and A8A, respectively, is identical to that of the pulse width modulation oscillator. The output from each reference oscillator is a 5 volt peak-to-peak triangular wave.

The triangular wave output of the pulse width modulation oscillator is applied to two VCAs via divider networks R17/R18 and R23/R24. These VCAs utilize current controlled CA3080s as multipliers. Since the output of the CA3080s is proportional to the product of the input voltage and the bias current flowing into pin 5, current injected on the PWMHN and PWMLN lines control the amount of triangular current appearing at the outputs (pin 6) of A9 and A11. Currents on these two input control lines are translated to the bias input terminals of the CA3080s via the current level translator circuits comprised of A10A/Q4 and A10B/Q5. Operation of these current level translators is identical to that of A1A and Q1 described previously. The output currents from amplifiers A9 and A11 modulate the control lines on the mother boards to determine the pulse width for the upper four and lower two octave sections of the keyboard, respectively. The control currents on the PWMHN and PWMLN lines are determined by the front panel controls and pulse width modulation high and low balance trim pots. R15 and R21 cancel any effects of input offset voltages of VCAs A9 and A11. The voltages applied to these VCAs are divided down by a factor of 100 to 1 by R17/R18 and R23/R24 networks so that the multiplier circuits are linear.

The output of reference oscillator No. 1 modulation oscillator at pin 7 of A5B is applied to a voltage controlled amplifier comprised of A13 and associated components. Operation of this circuit is identical to that described for pulse width modulation and oscillator modulation where balance trim pot R30 is used to cancel any input offset voltage of A13. Current injected on the POFMIN line controls the amount of frequency modulation current on the output pin of A13 which is applied to reference oscillator No. 1 summing amplifier A16A.



The triangular output voltage of A8B is applied to voltage controlled amplifiers A14 and A15 and are used to either phase-modulate or frequency-modulate reference oscillator No. 2. The output modulation current at pin 6 of A15 is applied to frequency control summing amplifier A18A for reference oscillator No. 2.

Current injected on the POFM2N line is applied to frequency modulation amplifier A15 via the current translation circuit comprised of A6B, Q7 and R43. This drive current is divided between the two amplifiers by R40 and R42, providing twice as much current to amplifier A15 as compared to amplifier A14. The current injected on the POFM2N line thus controls both the amount of frequency and phase modulation.

The output at pin 6 of A14 is applied to the ative input of A19 and a load resistor comprised of phase modulation balance trim pot R100 and resistor R99, the other end of which is connected to the sawtooth output of reference oscillator No. 1.

Operation of the two reference oscillators are identical, therefore only one will be described. The sawtooth outputs of the two reference oscillators are generated at pins 6 of A20 and A22 with 2 usec pulses appearing at pins 6 of amplifiers A21 and A23. Each reference oscillator is comprised of three subsections: (1) input summing and biasing networks; (2) an exponential and current converter; and (3) the oscillator section itself.

The input summing and biasing sections are comprised of amplifiers A16A/A16B and A18A/A18B.

Tuning control enters on the POFT line and is applied simultaneously to summing amplifiers A16A and A18A thru current sharing resistors R48 and R72 and thru R98 connected to the FINE TUNE control. BEAT rate control is introduced on the POBT line and is applied to reference oscillator No. 2 via R73. Control voltage RIBR from the pitch controller is applied to both oscillators via dead band diodes CR1 and CR2 and feed resistor R96. External oscillator control enters via the OSEXC line and is connected to both oscillators via R97. The various sources which control oscillator frequency are summed via A16A and applied to current converter drive amplifier A16B. Oscillator 1 range trim pot R51 is used for range tuning the reference oscillator and oscillator 1 scale trim pot R54 is used to trim the scale factor or frequency interval caused by various pitch control inputs and match the scaling of the two reference oscillators. The output of scaling amplifier A16B is applied to a heated differential transistor pair in IC1 via resistor R55. The transistor pair in IC1 is maintained at a constant temperature by internal circuitry. Current through the right hand transistor is constant. The collector of this transistor is maintained by A17B and associated components at a constant 5 volt reference potential which is also applied to the positive input of A17B via a network comprised of R63, R64 and R66 and input resistor R60. A17B maintains a 5 volt potential on pin 4 of IC1 via protection resistor R57 connected to the emitters. R59 and C11 are a high frequency roll-off network used to prevent oscillation. The voltage applied to pin 1 of IC1 causes an exponential current to be applied to the negative input of oscillator integrator amplifier A20. The FET switch in IC3 across capacitors C13 and C14 is normally open. Current drawn from the negative input of A20 causes the positive going ramp waveform on the output which is applied to the positive input of comparator A21, also supplied by a 5 volt reference potential via divider R63, R64 and R66.

Fast positive feedback provided by C17 and R6 to the positive input of A21 forces the output of A21 to switch very rapidly from 0 to 15 VDC switching the FET across C13 and C14 on. This action causes the voltage across C13 and C14 to drop to zero resetting the sawtooth waveform. The output of A20 drops to zero resetting the comparator output at pin 6 of A21 to zero, turning off the FET contained in IC3. This cyclical action results in a repetitive sawtooth of 5 volts amplitude on pin 6 of A20. Resistor R62 provides reset time compensation of the integrator so that the output frequency will be a linear function of current flowing into the negative input of A20. Capacitor C12 provides high frequency compensation to prevent oscillation and the output reset pulse duration on pin 6 of A21 is 2.0 usec.

The 2.0 usec output of reference oscillator No. 1 from pin 6 of A21 is applied through R69 to the phase comparator section of phase-locked loop IC6, a CMOS CD4046. IC6 compares the frequency of pulses from reference oscillator No. 1 and the return divided down clock line CLKC1 (from the frequency divider board) and provides a control voltage on line CLKC2 connected to a high frequency oscillator contained on the high frequency oscillator board.

The high frequency oscillator is slaved in a manner such that its divided down signal phase is exactly equal to that of reference oscillator No. 1.

In a similar manner, the output pulse from reference oscillator No. 2 (on pin 6 of A23) is applied to a phase comparator in IC7 via G3, G4 and R95, the active path when the instrument is in the FREE mode, in which case the two high frequency oscillator sections are independently synchronized to their respective reference oscillators. However, when the instrument is in the LOCK mode, the phase comparator in IC7 is fed from the output of a phase modulator circuit via G1 and G4. This phase modulator circuit is comprised of A19, load resistor R99 and phase modulation balance trim pot R100. Switching between the LOCK and FREE modes is accomplished via the SPLFR line which drives a level translator followed by an inverter in IC4 which drives gates G1 and G2 of IC5. When the SPLFR line is a "1" (LOCK mode), output pin 12 of IC4 is positive inhibiting G3 via inverter G2. At the same time, G1 is enabled as is the upper FET transistor in IC3 enabling a variable width pulse from A19 to be coupled to G1 and subsequently to IC7 via G4.

A 2.5 volt potential is applied to the positive input of A19 via a resistor divider network comprised of R63, R64 and R66. The potential appearing at pin 2, the negative input of A19, is the sum of the 5 volt sawtooth from reference oscillator No. 1 and the triangular phase modulation signal from VCA A14 described previously. A19 operates as a comparator at a threshold voltage of 2.5 volts and triggers at a variable point along the sawtooth depending upon the amplitude of the phase modulation current from A14. This action results in an output with a delay or advance from the leading edge of the reference signal (which is frequency locked to reference oscillator No. 1 but phase modulated). Since the phase comparator in IC7 triggers on the leading edge, the phase lock loop for the rank 2 oscillator system in the LOCK mode is synchronized but phase modulated relative to reference oscillator No. 1.

The 2 usec pulses from the two reference oscillators are applied to the BEAT rate indicator circuit comprised of IC8, Q8, front panel LED L1 and associated components. The reference frequency pulses are buffered by gates G5 and G6 and applied to a cross-coupled latch comprised of G7 and G8. This coupling scheme results in a flip-flop output on pin 3 of IC8 of a variable duty cycle depending upon the relative phase of reference oscillators No. 1 and 2. This pulse width modulated signal is applied through a simple filter circuit comprised of R135 and C26 and applied to the transistor amplifier comprised of R136 and Q8 which drives the front panel LED via limit resistor R137. This circuit generates a blink rate equal to the frequency difference between the two reference oscillators.

The drive level limit circuit is comprised of A24B, A24A and associated resistors. Current injected on the PLCMN line causes the output of A24A to vary between approximately -3 and 0 VDC. Trim pot R108 adjusts the drive level limit to the proper bias. The drive level limit output on pin 1 of A24A is applied to the contour capacitors contained on the mother board modulator boards via a diode. This diode clamp prevents overdrive of the contour signals on the modulator boards.

The sawtooth level output generated on the modulator boards is controlled via buss lines SWLBL, SWLBM and SWLBH, the control lines for the low, medium and high mother boards, respectively. These buss lines are driven by two sawtooth level circuits comprised of A25B, A25A, CR5, CR6 and associated components. Control currents for the sawtooth level from the front panel are injected on lines PSWLN and PSWHN and applied to amplifiers A25B and A25A. Sawtooth level high and low trim pots R114 and R120 provide bias control for setting the zero sawtooth level accurately. When the sawtooth waveform is switched off for either the lower or upper keyboard via the keyboard waveshape digital controls on the front panel, the appropriate control line, either SKO1H or SKO1L, is positive. This action causes current to be supplied to the sawtooth level amplifiers via CR5/R116 and CR6/R122 driving the amplifier outputs hard negative (about -12 VDC).

Decay rate control of the contour generators contained on the mother board modulator boards is accomplished via the KBLDB, KBMDB and the KBHDB buss lines which are connected to the low, medium and high mother boards, respectively. Currents provided by the front panel control and injected on lines PKDLN and PKDHN generate control voltages on buss lines via amplifiers comprised of A26A, A26B and A27, respectively. Decay low and medium set trim pots R126 and R127 adjust the operating points of these control circuits for the low and high keyboard sections, respectively. Decay high set trim pot R132 allows for a small amount of offset between

control voltages applied to the medium and high mother boards.

Pulse Width Control of the rectangular waveshape generated by the modulator boards is accomplished via the PWSLB, PWSMB and PWSHB buss lines for the low, medium and high mother boards, respectively. Currents provided by the front panel control and injected on the PSLN, PSMN and PSHN lines determine the voltages appearing on these buss lines. Pulse width trim pots R152, R145 and R138 set the operating points for the low, medium and high control lines, respectively. In addition, pulse width modulation currents are coupled to input amplifiers via resistors R144, R151 and R158. Resistors R144 and R151 set a 2 to 1 division of current provided by pulse width modulation VCAs resulting in twice as much pulse width modulation on the high mother board as on the medium mother board.

The polyphonic keyboard system is comprised of two buss lines (highest level, KBHLB and lowest level, KBLLB) with 71 parallel RC networks connected between them. The lowest level buss line is voltage driven while the highest level line is driven by a current source. The signal appearing on the lowest level buss is a composite d-c baseline and a 20 kHz carrier pulse train of variable width and variable height pulses. The height of the carrier pulse train determines the sustain level in the modulator boards while the carrier pulse width determines the attack time and the d-c level determines the amount of dynamic effect. Refer to Figure 4-1.

Gate G9 of IC9, R178 and C34 comprise a 20 kHz oscillator to drive gate G10 serving as a current shunt across intergrating capacitor C35. Capacitor C35 is shorted to ground during approximately 40 percent of the 20 kHz duty cycle. When open collector gate G10 goes off, current provided via the collector of Q10 causes the voltage to rise across C35 until gate G12 of IC9 fires via Darlington buffer Q13. When G12 fires, it shuts down gate G13 of IC10 just previously turned on via gate G11. The greater the current applied to C35, the more rapidly G12 fires producing a shorter pulse. If transistor Q10 is cut off so that no integration current is supplied to C35, G13 goes on and off as G9 goes on and off via gate G11. Thus, this circuit can never go to zero pulse width. The output of NAND gate G13 of IC10 is applied to open collector inverter G14 resulting in a variable width open collector time on pin 11 connected to the collector of current source transistor Q12. Control of this pulse width is accomplished by a current from a front panel control injected from the PKATN line and applied to amplifier A32A. This amplifier in turn drives differential pair Q10 and Q11 providing an exponential current to integration capacitor C35. The operation point of this circuit may be varied with attack set trim pot R165 to compensate for transistor offsets.

The SUSTAIN LEVEL is determined by current from the front panel control injected on the PKBSN line and applied to a current converter circuit comprised of A32B, Q12 and associated resistors. This circuit provides an approximate 20 to 1 current multiplication determined by the ratio of R175 and R177 and is biased via sustain level set trim pot R174. The multiplied current is applied to current level translator transistor Q15 which translates this current to R189, the lowest level load resistor. However, this current is shunted at a 20 kHz rate by open collector gate G14 of IC10 for a duty cycle determined by the attack time controls. Thus the voltage appearing on load resistor R189 is a pulse whose height is determined by sustain current and whose width is determined by attack current.

The degree of keyboard dynamics is determined by a current provided by the front panel DYN control and is injected on the PKDYN line connected to a current multiplier circuit comprised of A31A, Q14 and associated resistors. This multiplied current is applied to the previously mentioned load resistor R189 to introduce d-c offset. Lowest level trim pot R182 provides for lowest d-c operating level adjustment. The composite voltage on load resistor R189 is applied to emitter follower Q16 and R190 which drives the lowest level buss via R192.

The highest level buss, KBHLB, is coupled to the lowest level buss, KBLLB, with 71 parallel RC networks and presents an effective load resistance of approximately 330 ohms paralleled with 15 microfarads. The highest level detector and regulator circuit comprised of A31B, Q9, CR9, CR10 and associated components is a regulated current source which maintains peak voltage on the highest level (KBHLB) buss at approximately 3.0 VDC. The minus input of A31B is biased at +2.3 volts via a divider network comprised of R161 and R160. Feedback resistor R162 sets an amplifier gain of 100 with respect to signals appearing on the positive input and the output of A31B drives the current source comprised of R163 and Q9. If, for example, the highest level buss

voltage is significantly below +3.0 VDC, then the positive input of A31B is pulled toward ground via R164. The resulting voltage difference on the input of A31B is amplified by a gain of 100 which drives the output of A31B negative, turning on the current source. The current source, comprised of R163 and Q9, supplies current via CR9 to the highest level buss. The voltage on the highest level buss rises until voltage on the input of A31B is 2.3 volts. This occurs when voltage on the highest level buss is approximately 3

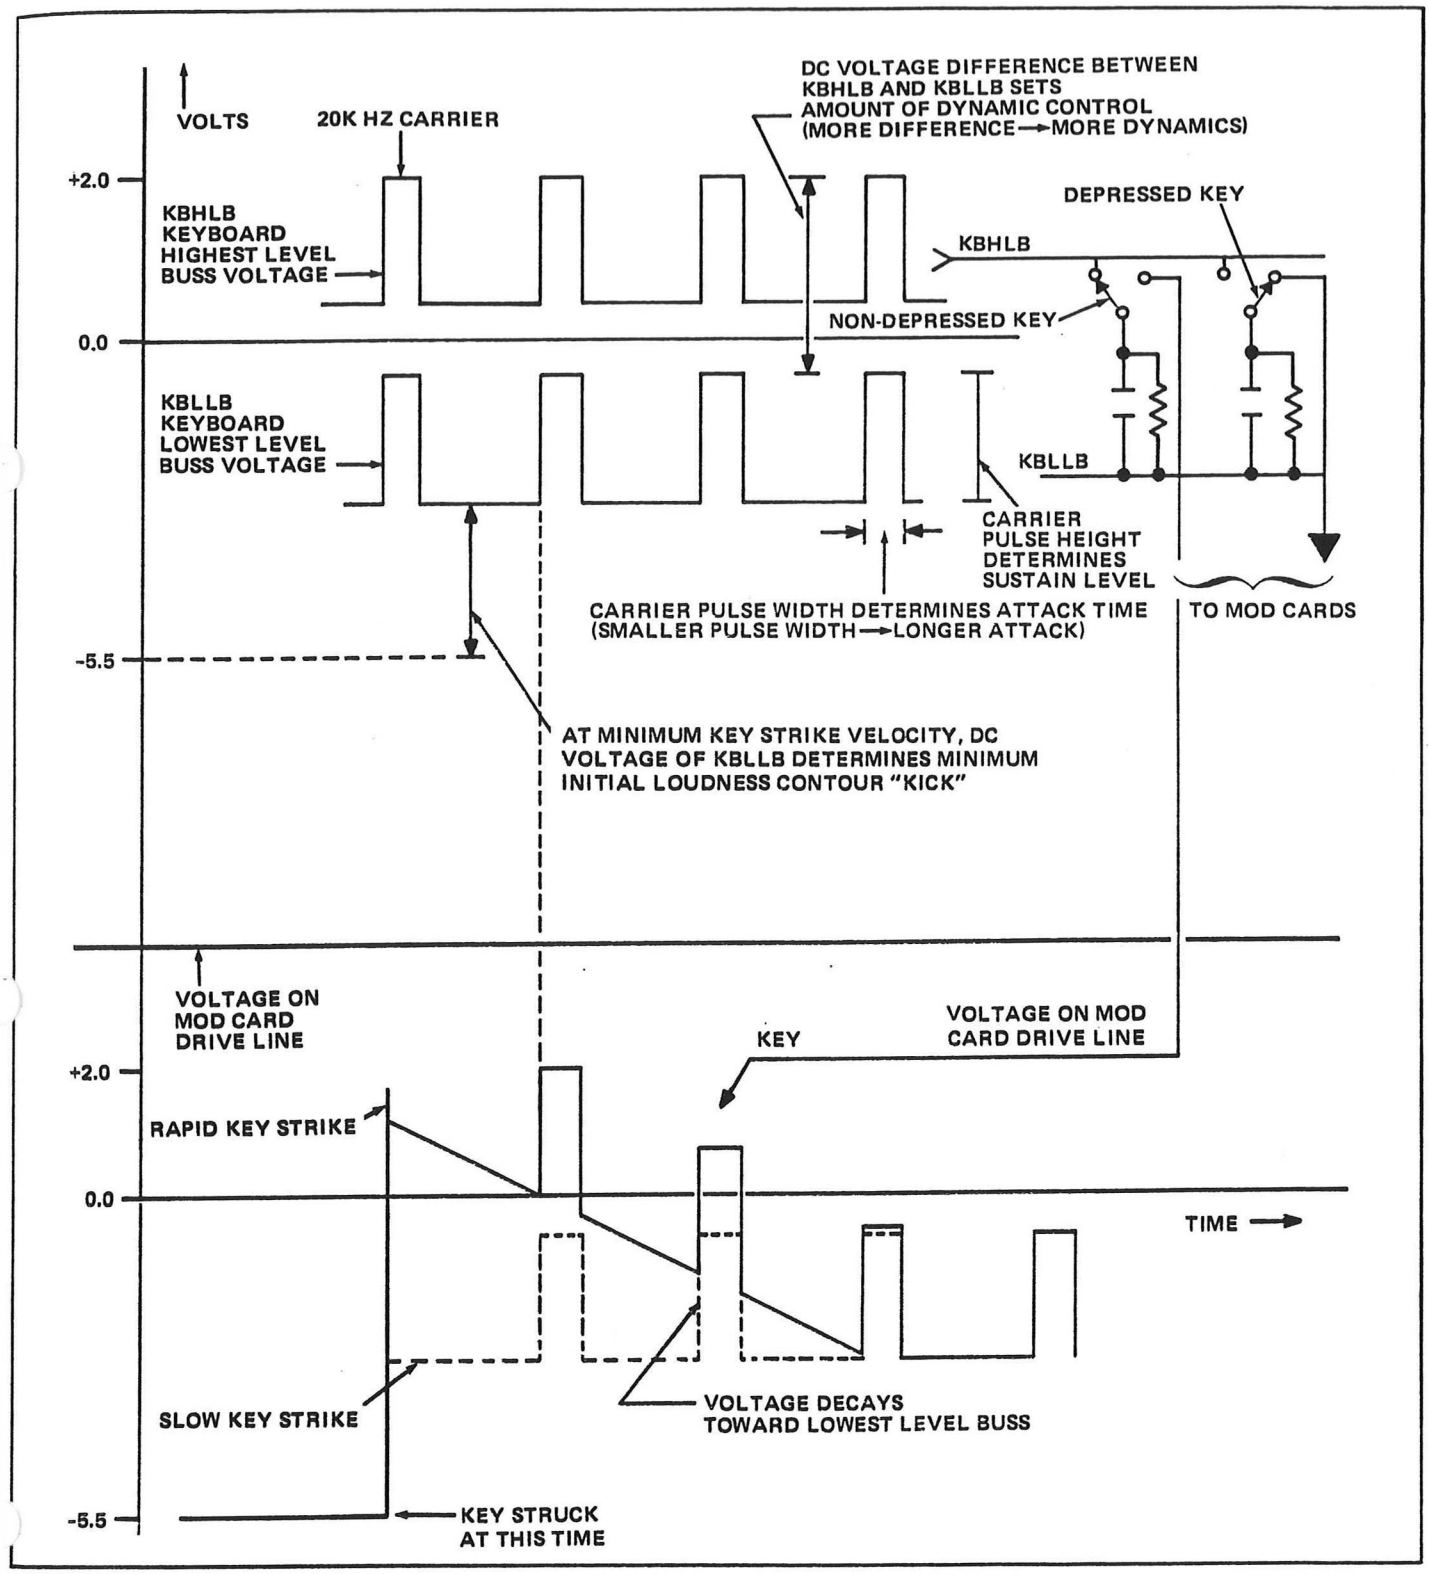


FIGURE 4-1 POLYMOOG AND POLYMOOG KEYBOARD CONTROL CIRCUITS

VDC because of an additional voltage drop across diode CR10. If, for example, the lowest level control current is increased, causing the potential across Q15 and resistor R189 to rise and thereby causing the lowest level voltage to rise, the voltage applied to the positive input of A31B begins to rise shutting down the current source via Q9 lowering the voltage on the highest level buss. The maximum keyboard dynamic effect occurs when the voltage difference between the highest level and lowest level busses is at maximum. As voltage on the lowest level buss is increased, this voltage difference decreases. When a key is depressed, the associated RC network on the keyboard is detached from the highest level buss and, after a transit time (inversely proportional to the velocity) contacts the key drive input connected to the associated modulator board. The original d-c voltage difference between the lowest and highest level busses is applied to the RC network and decays toward zero with a time constant of 5 msec. The more rapidly a key is depressed, the higher this voltage difference and the higher the voltage "kick" applied to the associated modulator board. When the lowest level voltage is high to start with, the voltage difference between the lowest and highest level busses is small and the d-c voltage kick to the modulator board is large but it does not change with velocity because there is no voltage difference across the parallel RC network to begin with. In this case, a fixed kick is applied to the modulator board and there is no dynamic effect.

Both sustain level drive and lowest level drive apply current to lowest level load resistor R189 raising its potential. However raising both of these to a maximum could cause the peak voltage on the lowest level output to exceed the voltage set by the highest level detector and regulator. This condition would cause the keyboard to have a reverse dynamic effect. To eliminate this "pile up" problem and yet maintain the ability of either the lowest level drive or the sustained level drive to achieve maximum drive when the other is a minimum, the peak voltage of the lowest level buss is regulated to a maximum voltage of +0.7 VDC by the lowest level detector and regulator circuitry comprised of CR11, A33, CR12 and associated components. Diode CR11, C38 and R192 comprise a peak detector driving an amplifier with a gain of 47 comprised of A33, R193 and R191. Additional smoothing of the peak detector output is accomplished by C39. If the voltage on the lowest level buss (emitter of Q16) begins to exceed 0.7 VDC, the output of A33 swings negative with a gain of 47. This voltage provides current via CR12 and R194 to lowest level drive amplifier A31A shutting down current delivered via the collector of Q14 to lowest level load resistor R189 and back to the lowest level buss via emitter follower Q16. As mentioned previously, this feedback prevents overdrive of the lowest level output buss.

4.2 GENERAL SERVICING

The most sensitive components are the CA3080s and CMOS ICs which plug into sockets for easy replacement. Improper operation of a particular circuit block may be due to either a malfunction on the board itself or to an improper control signal entering the board. In many cases, this can be determined simply by removing the connector which carries the input control signal. All connectors may be removed from the left hand board and the unit turned on (except power supply connector P710 in serial numbers up to 2350 as this connector carries the sense lines for the 15 volt buss supply).

> **NOTE**
> The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting and alignment procedures and after replacement of all malfunctioning parts. Whenever a CA3080 integrated circuit is replaced, repeat alignment of the specific circuit affected as indicated in paragraphs 4.4 for Polymoog or 4.5 for Polymoog Keyboard.

4.3 ALIGNMENT

All trim adjustments for the top left board are available by removing the top cover. (Refer to Figure 4-2).

4.4 POLYMOOG TUNING AND ADJUSTMENT

> **NOTE**
> Before performing any adjustment, the following power supply voltages must be checked first with at least a 3-1/2 digit digital voltmeter: +15V, -15V, +5V, +4.85V and -5.5V.

a. PULSE WIDTH MODULATION HIGH BALANCE ADJUSTMENT

1. Depress ⎍⎍ SHAPE/MODULATION VAR pushbutton and place all five slide controls full up.

2. Short pin 5 of A3B to ground. Connect DVM to pin 6 of A9 and adjust trim pot R15 for an indication of 0.0 ± 0.02 VDC.

3. Remove short at pin 5 of A3B and disconnect voltmeter.

b. PULSE WIDTH MODULATION LOW BALANCE ADJUSTMENT

1. Depress ⎍⎍ SHAPE/MODULATION VAR pushbutton and place all five slide controls full up.

2. Short pin 5 of A3B to ground. Connect DVM to pin 6 of A11 and adjust trim pot R21 for 0.0 ± 0.010 VDC.

3. Remove short at pin 5 of A3B and disconnect DVM.

c. OSCILLATOR 1 MODULATION AMOUNT ADJUSTMENT

1. Depress ⩘ FM VAR pushbutton and place all four slide controls full up.

2. Short pin 5 of A5B to ground. Connect DVM to pin 6 of A13 and adjust trim pot R30 for an indication of 0.0 ± 0.005 VDC.

d. FM 2 MODULATION AMOUNT ADJUSTMENT

1. Depress ⩘ FM VAR pushbuttons and place all four slide controls full up.

2. Short pin 5 of A8B to ground. Connect DVM to pin 6 of A15 and adjust trim pot R38 for an indication of 0.0 ± 0.005 VDC.

3. Remove short at pin 5 of A8B and disconnect DVM.

e. OSCILLATOR 2 MODULATION AMOUNT ADJUSTMENT (Also, see Step j)

1. Depress ⩘ FM VAR pushbutton and place all four slide controls full up.

2. Short pin 5 of A8B to ground and turn trim pot R100 fully clockwise for maximum resistance. (If blue or metal trim pots are used, turn R100 counterclockwise.)

3. Short junction of R99 and R100 to ground. Connect DVM to pin 6 of A14 and adjust trim pot R35 for an indication of 0.0 ± 0.010 VDC.

4. Remove shorts at pin 5 of A8B and junction of R99 and R100 and disconnect DVM. Perform phase modulation amount adjustment as directed in step i to obtain proper amount of phase modulation.

f. OSCILLATOR 1 RANGE ADJUSTMENT

1. Center trim pot R54 and front panel FINE TUNE and BEAT controls at far left of instrument panel.

2. Depress preset No. 8 and ⩘ FM VAR pushbuttons. Place all four ⩘ FM slide controls full down.

3. Monitor output, depress note A_4 and adjust trim pot R51 for an output frequency of 440 ± 1Hz.

g. OSCILLATOR 1 SCALE ADJUSTMENT

1. Adjust trim pot R54 for a normal center position.

h. OSCILLATOR 2 RANGE AND SCALE ADJUSTMENT

1. Center front panel FINE TUNE and BEAT controls.

2. Depress preset No. 8 and ⩘ FM VAR pushbuttons. Place all four ⩘ FM slide controls full down.

3. Depress KEYBOARD ⎍⎍ WAVESHAPE LOWER/UPPER pushbuttons.

4. Monitor output, depress note Eb_4 (622.2 Hz), depress high point of RIBBON PITCH CONTROLLER and zero beat by adjusting ten turn trim pot R76 (Oscillator No. 2 RANGE).

5. Check oscillator scaling by observing BEAT RATE LED for a rate of 0Hz. Release RIBBON PITCH CONTROLLER and adjust R80 (scale trim pot for zero beat).

6. Repeat procedure until zero beat is observed on both center and upper positions.

i. PHASE MODULATION AMOUNT ADJUSTMENT (also, see step j)

1. Depress preset No. 1 and ⩘ FM VAR pushbuttons. Place all four ⩘ FM slide controls full up and trim pot R100 fully counterclockwise (clockwise if blue or metal trim pots).

2. Observe output at pin 6 of A19 using an oscilloscope triggered on the leading edge of the signal at pin 6 of A19.

3. Rotate trim pot R100 slowly clockwise (counterclockwise if blue or metal trim pots) noting

pulse width variation becomes narrower and narrower toward zero at various times. Adjust trim pot R100 so that the minimum pulse width is approximately percent of the total duty cycle and disconnect oscilloscope.

j. ALTERNATE PHASE MODULATION AMOUNT ADJUSTMENT

1. Depress preset No. 8, upper ⎍⎍ waveshape, ⎍⎍ FM/PM VAR, LOCK, Key A4 (A440) and adjust RATE and AMOUNT to 10. Turn trim pot R100 fully clockwise (counterclockwise if blue or metal trim pots) and listen while turning counterclockwise until a smooth modulation is just present.

k. DRIVE LIMIT LEVEL ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 1 of A24A.
2. Adjust trim pot R108 for an indication of -4.1 ± 0.050 VDC and connect P72.

l. SAWTOOTH LEVEL HIGH ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 7 of A25B.
2. Adjust trim pot R114 for an indication of -5.1 ± VDC and connect P72.

m. SAWTOOTH LEVEL LOW ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 1 of A25A.
2. Adjust trim pot R120 for an indication of -5. ± 0.1 VDC and connect P72.

n. DECAY LOW SET ADJUSTMENT

1. Unplug connector P75 from board and monitor voltage at pin 7 of A26B.
2. Adjust trim pot R126 for an indication of -3.74 ± 0.020 VDC and connect P75.

o. DECAY MEDIUM SET ADJUSTMENT

1. Unplug connector P75 from board and monitor voltage at pin 1 of A26A.
2. Adjust trim pot R127 for an indication of -3.74 ± 0.020 VDC and connect P75.

p. DECAY HIGH SET ADJUSTMENT

1. Unplug connector P 75 from board and monitor voltage at pin 6 of A27.
2. Adjust trim pot R132 for an indication of -3.64 ± 0.020 VDC and connect P75.

q. PULSE WIDTH HIGH SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A28A.
2. Adjust trim pot R138 for an indication of -9.00 ± 0.050 VDC and connect P77 and P72.

r. PULSE WIDTH MEDIUM SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A29A.
2. Adjust trim pot R145 for an indication of -9.00 ± 0.050 VDC and connect P77 and P72.

s. PULSE WIDTH LOW SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A30A.
2. Adjust trim pot R152 for an indication of -9.00 ±0.050 VDC and connect P77 and P72.

t. ATTACK SET ADJUSTMENT

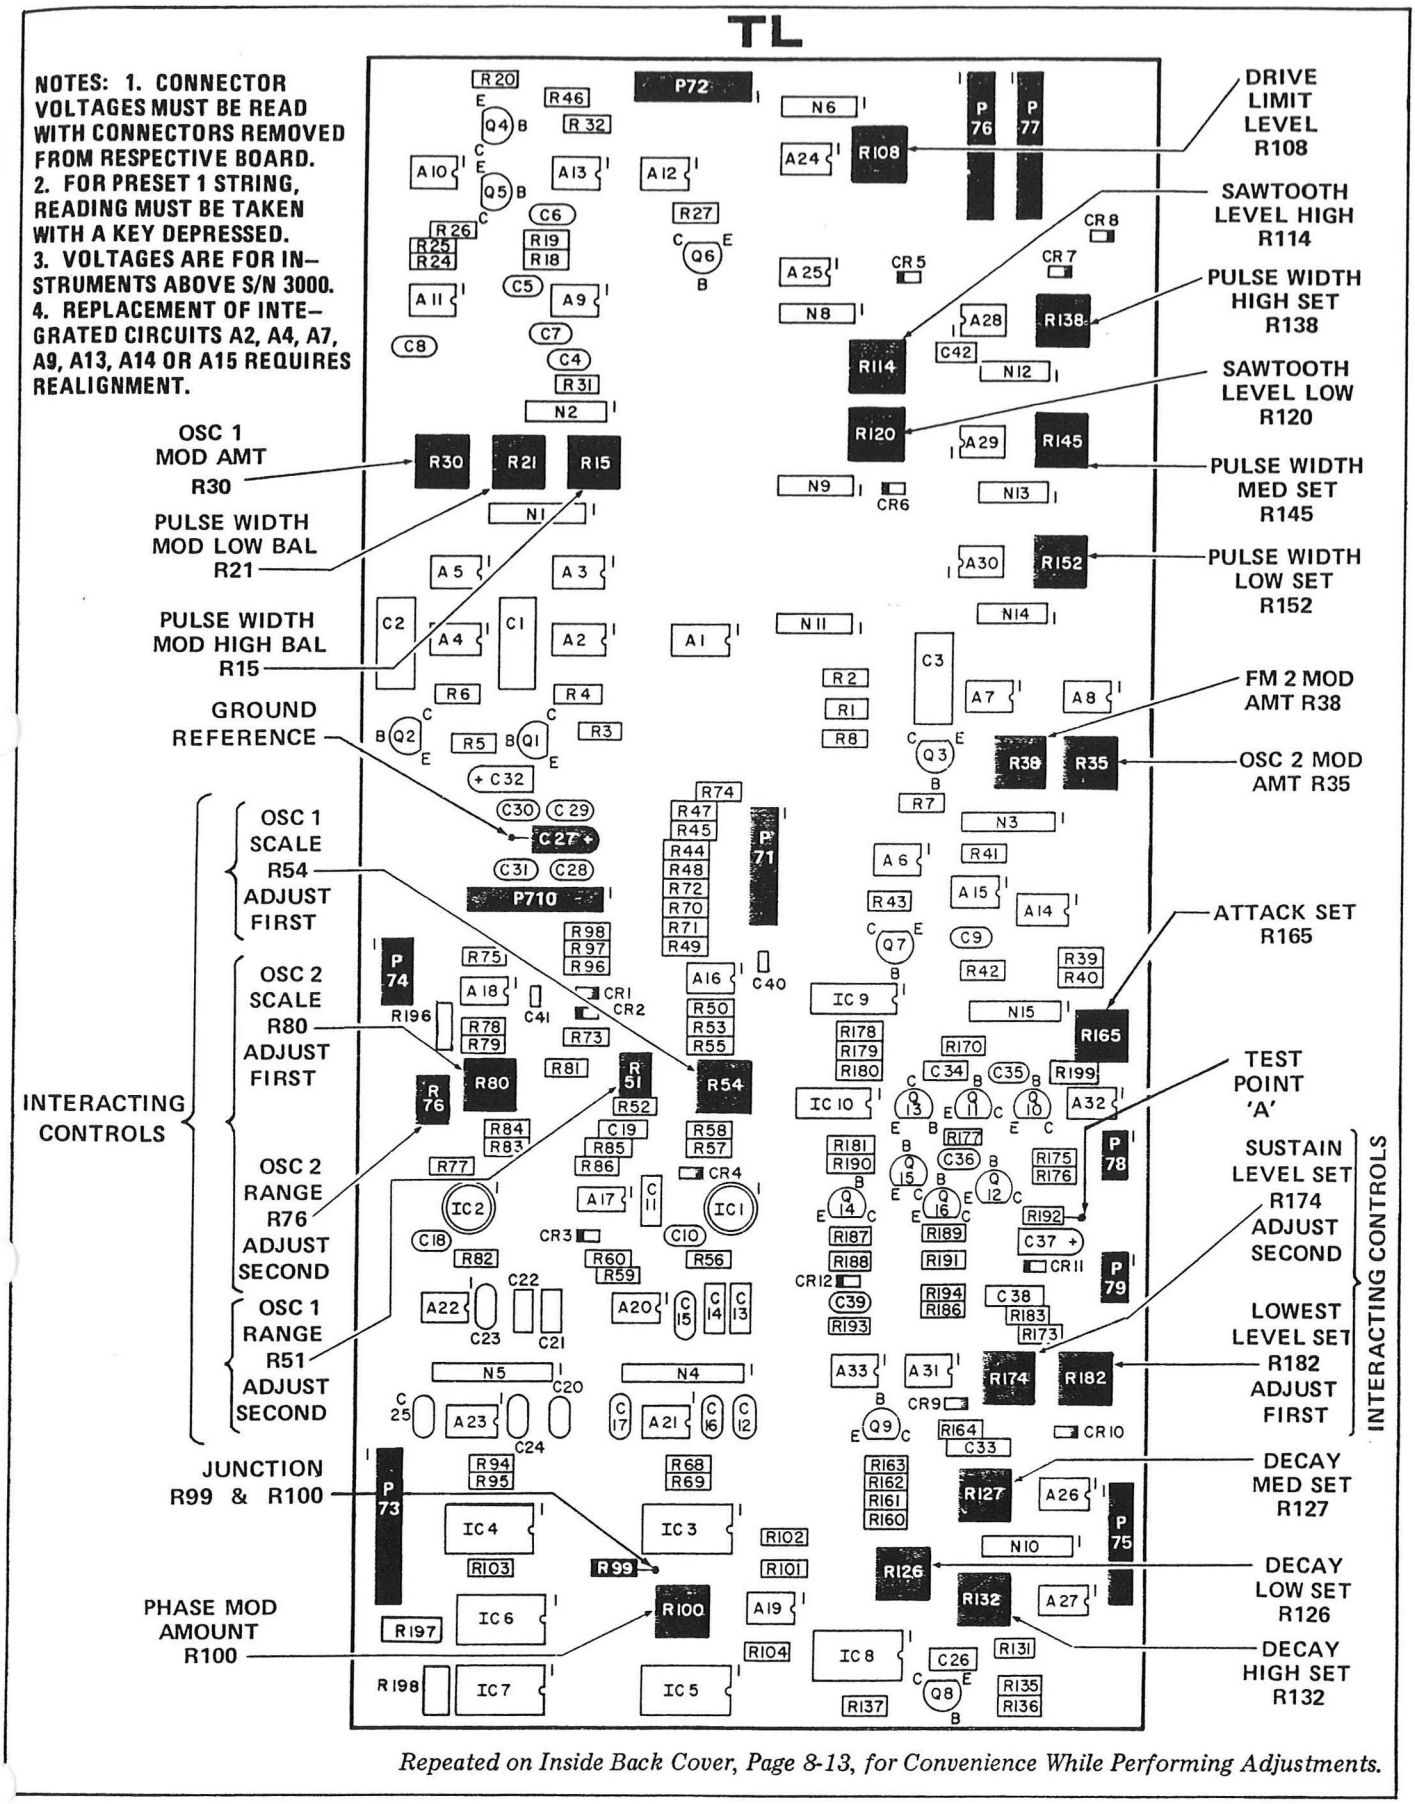
1. Unplug connector P78 from board and monitor waveform at pin of IC10A with an oscilloscope.
2. Adjust trim pot R165 so that the pulse at pin 1 just barely disappears (zero pulse width) and connect P78.

u. SUSTAIN LEVEL SET ADJUSTMENT

1. Unplug connector P78 from board and monitor a 20kHz square wave at pin 1 of P79 or test point "A" at R192 (Figure 4-2) with an oscilloscope.
2. Adjust trim pot R174 so that the peak-to-peak voltage of this waveform is 1.2 ± 0.050 volts and connect P78.

v. LOWEST LEVEL SET ADJUSTMENT

1. Unplug connector P78 from board and monitor voltage at pin 1 of P79 (test point "A" at R192).
2. Short pin 11 of IC10B or Q15 emitter to ground and adjust trim pot R182 for an indication of -3.60 ± 0.030 VDC. Remove short and connect P78.



Repeated on Inside Back Cover, Page 8-13, for Convenience While Performing Adjustments.

FIGURE 4-2 REFERENCE AND MODULATION OSCILLATOR WAVESHAPE AND KEYBOARD CONTROL PRINTED CIRCUIT BOARD ASSEMBLY

4.5 POLYMOOG KEYBOARD TUNING AND ADJUSTMENT

a. PULSE WIDTH MODULATION HIGH BALANCE ADJUSTMENT

1. Depress preset No. 12 and MODULATION VAR pushbuttons. Place both slide controls full up.
2. Short pin 5 of A3B to ground. Connect DVM to pin 6 of A9 and adjust trim pot R15 for an indication of 0.0 ± 0.02 VDC.
3. Remove short at pin 5 of A4B and disconnect DVM.

b. PULSE WIDTH MODULATION LOW BALANCE ADJUSTMENT

1. Depress preset No. 12 and MODULATION VAR pushbuttons. Place both slide controls full up.
2. Short pin 5 of A3B to ground. Connect DVM to pin 6 of A11 and adjust trim pot R21 for 0.0 ± 0.010 VDC.
3. Remove short at pin 5 of A3B and disconnect DVM.

c. OSCILLATOR 1 MODULATION AMOUNT ADJUSTMENT

1. Depress preset No. 2 and MODULATION VAR pushbuttons. Place both slide controls full up.
2. Short pin 5 of A5B to ground. Connect DVM to pin 6 of A13 and adjust trim pot R30 for an indication of 0.0 ± 0.005 VDC.
3. Remove short at pin 5 of A5B and disconnect DVM.

d. FM 2 MODULATION AMOUNT ADJUSTMENT

1. Depress preset No. 7 and MODULATION VAR pushbuttons. Place both slide controls full up.
2. Short pin 5 of A8B to ground. Connect DVM to pin 6 of A15 and adjust trim pot R38 for an indication of 0.0 ± 0.005 VDC.
3. Remove short at pin 5 of A8B and disconnect DVM.

e. OSCILLATOR 2 MODULATION AMOUNT ADJUSTMENT

1. Depress preset No. 7 and MODULATION VAR pushbuttons. Place both slide controls full up.
2. Short pin 5 of A8B to ground and turn trim pot R100 fully clockwise. (If blue or metal trim pots are used, turn R100 counterclockwise.)
3. Short junction of R99 and R100 to ground. Connect DVM to pin 6 of A14 and adjust trim pot R35 for an indication of 0.0 ± 0.010 VDC.
4. Remove shorts at pin 5 of A8B and junction of R99 and R100 and disconnect DVM. Perform phase modulation amount adjustment as directed in step i to obtain proper amount of phase modulation.

f. OSCILLATOR 1 RANGE ADJUSTMENT

1. Center trim pot R54 and front panel FINE TUNE and BEAT controls at far left of instrument panel.
2. Depress preset No. 9 and MODULATION VAR pushbuttons. Place two slide controls full down.
3. Monitor output, depress note A4 and adjust trim pot R51 for an output frequency of 440 ± 1Hz.

g. OSCILLATOR 1 SCALE ADJUSTMENT

1. Adjust trim pot R54 for a normal center position.

h. OSCILLATOR 2 RANGE AND SCALE ADJUSTMENT

1. Center front panel FINE TUNE and BEAT controls.
2. Depress preset No. 4 and MODULATION VAR pushbuttons. Place both slide controls full down.
3. Monitor output, depress note Eb_4, depress high point of RIBBON PITCH CONTROLLER and zero beat by adjusting ten turn trim pot R76.
4. Check oscillator scaling by observing BEAT RATE LED for a rate of 0Hz. Release RIBBON PITCH CONTROLLER and adjust R80 (scale trim pot) for zero beat.
5. Repeat procedure until zero beat is observed on both center and upper positions.

i. PHASE MODULATION AMOUNT ADJUSTMENT

1. Depress preset No. 14 and MODULATION VAR pushbuttons. Place both slide controls full up

and trim pot R100 fully counterclockwise (clockwise if blue or metal trim pots).

2. Observe output at pin 6 of A19 using an oscilloscope triggered on the leading edge of the signal at pin 6 of A19.

3. Rotate trim pot R100 slowly clockwise (counterclockwise if blue or metal trim pots) noting pulse width variation becomes narrower and narrower toward zero at various times. Adjust trim pot R100 so that minimum pulse width is approximately 10 percent of the total duty cycle and disconnect oscilloscope.

j. DRIVE LIMIT LEVEL ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 1 of A24A.

2. Adjust trim pot R108 for an indication of -4.1 ± 0.050 VDC and connect P72.

k. SAWTOOTH LEVEL HIGH ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 7 of A25B.

2. Adjust trim pot R114 for an indication of -5.1 ± 0.1 VDC and connect P72.

l. SAWTOOTH LEVEL LOW ADJUSTMENT

1. Unplug connector P72 from board and monitor voltage at pin 1 of A25A.

2. Adjust trim pot R120 for an indication of -5.1 ± 0.1 VDC and connect P72.

m. DECAY LOW SET ADJUSTMENT

1. Unplug connector P75 from board and monitor voltage at pin 7 of A26B.

2. Adjust trim pot R126 for an indication of -3.74 ± 0.020 VDC and connect P75.

n. DECAY MEDIUM SET ADJUSTMENT

1. Unplug connector P75 from board and monitor voltage at pin 1 of A26A.

2. Adjust trim pot R127 for an indication of -3.74 ± 0.020 VDC and connect P75.

o. DECAY HIGH SET ADJUSTMENT

1. Unplug connector P75 from board and monitor voltage at pin 6 of A27.

2. Adjust trim pot R132 for an indication of -3.64 ± 0.020 VDC and connect P75.

p. PULSE WIDTH HIGH SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A28A.

2. Adjust trim pot R138 for an indication of -9.00 ± 0.050 VDC and connect P77 and P72.

q. PULSE WIDTH MEDIUM SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A29A.

2. Adjust trim pot R145 for an indication of -9.00 ± 0.050 VDC and connect P77 and P72.

r. PULSE WIDTH LOW SET ADJUSTMENT

1. Unplug connectors P77 and P72 from board and monitor voltage at pin 1 of A30A.

2. Adjust trim pot R152 for an indication of -9.00 ± 0.050 VDC and connect P77 and P72.

s. ATTACK SET ADJUSTMENT

1. Unplug connector P78 from board and monitor waveform at pin of IC10A with an oscilloscope.

2. Adjust trim pot R165 so that the pulse at pin 1 just barely disappears (zero pulse width) and connect P78.

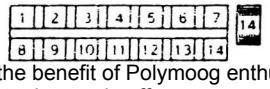
t. SUSTAIN LEVEL SET ADJUSTMENT

1. Unplug connector P78 from board and monitor a 20kHz square wave at pin 1 of P79 or test point "A" at R192 (Figure 4-2) with an oscilloscope.

2. Adjust trim pot R174 so that the peak-to-peak voltage of this waveform is 1.2 ± 0.050 volts and connect P78.

u. LOWEST LEVEL SET ADJUSTMENT

1. Unplug connector P78 from board and monitor voltage at pin 1 of P79 (test point "A" at R192).



2. Short pin 11 of IC10B or Q15 emitter to ground and adjust trim pot R182 for an indication of -3.60 ± 0.030 VDC. Remove short and connect P78.

4.6 REMOVAL

a. If it is necessary to remove a component, remove four screws located at the center and to the right of the board.

b. Raise board to gain bottom access noting it is hinged at the left side.

4.7 TROUBLESHOOTING

Troubleshoot the TL board using Table 4-1, the circuit description (paragraph 4.1), part location and schematic diagrams (Refer to Volume II). Note that voltage levels and waveforms displayed on the schematic diagram are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a digital voltmeter or oscilloscope to determine the malfunctioning part.

TABLE 4-1
POLYMOOG AND POLYMOOG KEYBOARD TL BOARD 7 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
No pulse width modulation UPPER AMT	A10A, Q4, A9*, N2, trim pot R15 not adjusted properly.
No pulse width modulation LOWER AMT	A10B, Q5, A11*, trim pot R21 not adjusted properly.
No pulse width modulation UPPER or LOWER AMT	A3, A2*, A1A, Q1, N1
No FM1 modulation	A12B, Q6, A13*, A5, A4*, A1B, Q2, trim pot R30 not adjusted properly.
No FM2 modulation but phase modulation	A15*, trim pot R38 not adjusted properly.
No phase modulation but have FM2 modulation	A14*, trim pot R35 not adjusted properly, N3
No FM2 modulation or phase modulation	A6B, Q7, A8, A7*, A6A, Q3
Reference oscillator No. 1 dead	A16, IC1, A17B, A20, A21, IC3, trim pots R51 and R54 not adjusted properly, N4
Reference oscillator No. 2 dead	A18, IC2, A17A, A22, A23, IC4, trim pots R76 and R80 not adjusted properly, N5
Reference oscillator No. 1 and 2 dead	A17
Phase modulation causes pitch glitching	Trim pot R100 adjusted too high or trim pot R35 misadjusted.
Reference oscillator No. 1 operates properly but high frequency oscillator on divider board does not synchronize	IC6
Reference oscillator No. 2 operates properly but does not sychronize when instrument is in FREE mode	IC5, IC4, IC7

* Replacement requires alignment.

TABLE 4-1

POLYMOOG AND POLYMOOG KEYBOARD TL BOARD 7 TROUBLESHOOTING (Continued)

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Instrument operates in FREE mode but does not in LOCK mode	A19, IC3, IC4, IC5
Drive level limit will not adjust or is wrong value	A24, trim pot R108, N6
Sawtooth level does not operate properly	A25B, CR5, N8, trim pot R114 not adjusted properly
Sawtooth level low does not operate properly or will not adjust	A25A, CR6, N9, trim pot R120
Decay low control does not operate properly or will not trim	A26B, trim pot R126, N10
Decay medium and decay high will not adjust properly	A26A, A27, N10, trim pots R127 and R132
Decay medium operates properly but decay high does not	A27, trim pot R132 not adjusted properly, N10
Reference oscillators operate properly but front panel BEAT rate LED does not	IC8, Q8, L1 (front panel)
Pulse width high cannot be trimmed or does not operate properly	A28, N12, trim pot R138, N11
Pulse width medium does not operate properly or cannot be trimmed	A29, N13, trim pot R145, N11
Pulse width low does not operate properly or cannot be trimmed	A30, N14, trim pot R152, N11
ATTACK time control does not operate properly or cannot be trimmed	IC9, IC10, Q13, A32A, Q10, Q11, N15, trim pot R165
DYNAMIC control does not operate properly	A31A, Q14, trim pot R182 not adjusted properly
SUSTAIN level does not operate properly or will not trim	A32B, Q12, IC9, IC10, Q10, Q11, Q13, trim pot R174
Noise or hash on highest or lowest level busses	A31, Q9, CR9, CR10, A33, CR12, CR11, Q15,Q16
Oscillator frequency increases as unit warms up	IC1, IC2
	* Replacement requires alignment.

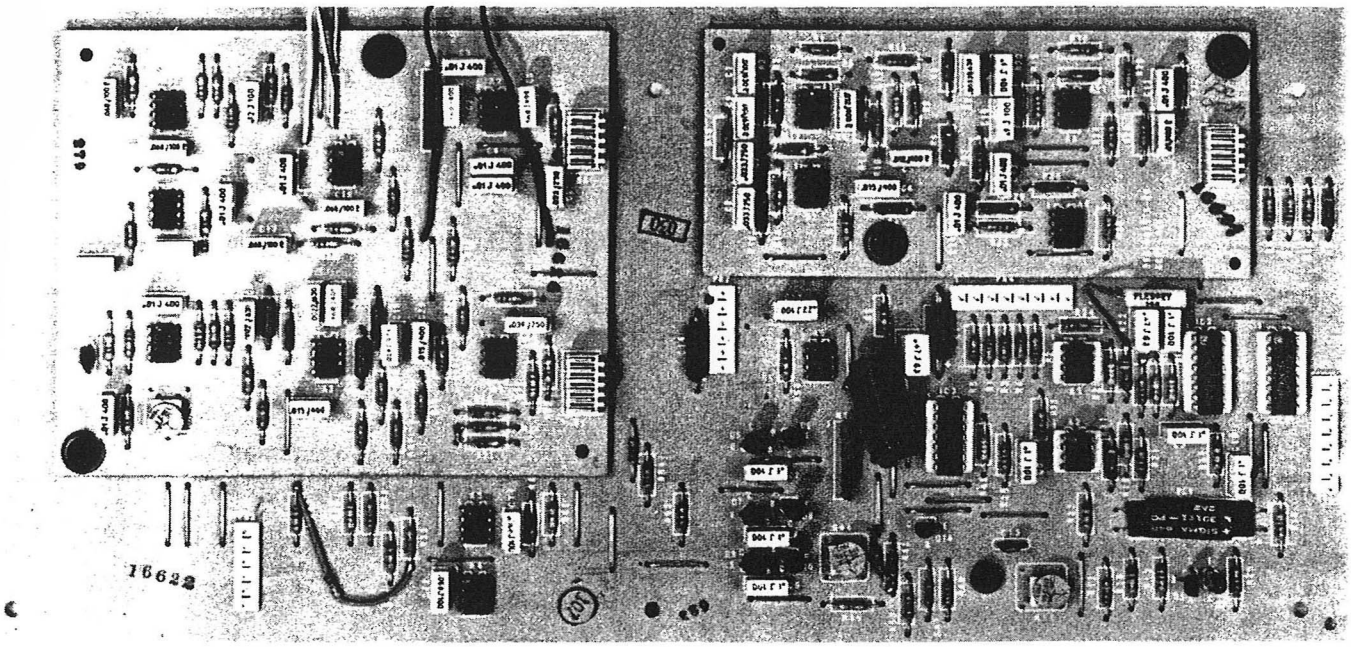
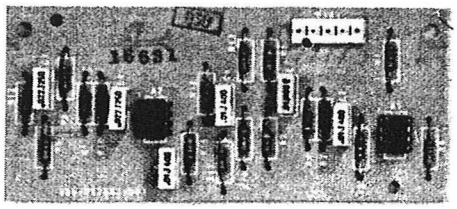
POLYMOOG FIXED AND VARIABLE RESONANT FILTERS BOARD 8



POLYMOOG KEYBOARD AUDIO CIRCUIT BOARD 8



POLYMOOG KEYBOARD
VOX HUMANA BOARD 14

SECTION 5
BOARDS 8 AND 14
FIXED AND VARIABLE RESONANT FILTERS AND VOX HUMANA
TC

5.1 CIRCUIT DESCRIPTION – POLYMOOG

The fixed and variable resonant filters printed circuit board No. 8 (TC) contains three basic circuit functions: (1) summing of mother board outputs for the DIRECT output; (2) MODE (preset) filtering for eight basic modes; and (3) a three band RESONANT filter where each filter has variable gain, cutoff and Q (resonance), low, band and high pass modes. (Refer to Volume II for schematic).

The audio signal outputs of the low, medium and high mother boards are applied directly to OCTAVE BAL controls R65 thru R67 on the front panel. The wipers of these three controls are connected to the OUTLW, OUTMW, and OUTHW lines which enter the TC board on pins 1 thru 3 of P83. These three audio signals are summed together by an inverting amplifier comprised of A1A and R5 thru R8, providing a composite audio signal applied to the top of the DIRECT gain slide control R3 in the MASTER GAIN CONTROLS section of the front via pin 6 of P82.

In addition, these mother board audio signals are applied to the low-high select gates in IC1 via R11 thru R13. The audio signals from the mother boards are biased at +4.85 VDC, the audio reference potential. The +15 VDC signal on the C (control) lines of IC1 opens the respective gate, so that, for example, if the upper keyboard section is selected, the SREH line is at +15 VDC and gates 1 and 2 are open, applying signals from the medium and high mother boards to buffer amplifiers A2A and A2B, respectively. These selected buffered mother board signals drive the preset gain adjust resistor networks N2 thru N4 and also resonator drive amplifier A3B via summing resistors R18 thru R20, gate 4 and IC1, which is held on at all times.

The resistors in networks N2 thru N4 are used to compensate for variations in signal levels coming from the mother boards when selecting different preset modes. Three corresponding resistors (one from each resistor pack) are applied to one of the eight inputs of the mode selector gates contained in IC2. IC2 is a CMOS analog multiplexer switch which routes one of the eight inputs to the common output, pin 3. The SPB1, 2 and 3 control lines applied to pins 11, 10 and 9 of IC2 contain a binary coded representation of the active preset mode and determine which one of the eight applied input signals is routed to the output on pin 3. The output of IC2 is connected to drive amplifier A4 which drives eight master preset filters in parallel. The eight master preset filter outputs are applied to a second 8 to 2 analog selector switch, IC3, whose output on pin 3 is connected via pin 4 of P82 to front panel MODE gain control R1 (in the MASTER GAIN CONTROLS section). This output selector is driven by the same SPB lines as is gain set selector, IC2.

Supply rails of +12.5 and -2.5 VDC for the selector switches in IC2 and IC3 are derived from networks comprised of R46 thru R48 and Q1 and R49, R50, R106 and Q2, respectively. Operation of the analog switches at these voltages allows for maximum signal voltage headroom, for if the voltage applied to one of the analog switch inputs should exceed the supply rails, it will leak through the selector gates even though the gate is turned off.

Three state-variable filters comprised of amplifiers A5 thru A9 are driven by buffer amplifier A3B which is driven by three drive amplifiers A2A, A2B and A3A via summing resistors R18 thru R20.

The three filters (RESONATORS) cover frequency ranges of 60 to 300 Hz, 300 to 1500 Hz, and 1500 to 7500 Hz. The drive signal from A3B is applied to three front panel GAIN slide controls R58, R68 and R80. The reference or ground side of these GAIN slide controls is connected to the audio reference rail (V_{ch} = +4.85 VDC) via pin 3 of P87. These GAIN slide controls apply a variable input to the state-variable filters. The 60 to 300 Hz resonator is comprised of A5A, A5B, A6A and associated components.

The input drive signal is applied to combining amplifier A5A driving an integrator comprised of the A element of 10K ohm dual linear pot R60, R56,

C2 and A5B in turn driving a second integrator comprised of the B element of 10K ohm dual linear pot R60, R57, C3 and A6A. Feedback is applied to the negative input of the combining amplifier via R51 and to the positive input of the combining amplifier via R54 from the first integrator. The high pass output is taken from output pin 1 of combining amplifier A5A, the band pass output is taken from the output of the first integrator, pin 7 of A5B and the low pass output is taken from pin 1 of A6A. The cutoff frequency is varied by 10K ohm dual linear pot R60. The Q or emphasis is varied by attenuating feedback applied to the positive input of combining amplifier A5A via R59 (a 10K ohm linear pot on the front panel labeled EMPH). The high and low pass ports have 12dB/0 CT cutoff slopes. The band pass has 6dB cutoff slopes.

Frequency scaling for the three filter sections is accomplished by varying the integrator capacitances. Corresponding outputs from each of the three filter sections are summed together in resistor networks N8 and N9 and applied to the filter mode selector switches contained in IC4, a CMOS analog switch. The E (equalization) mode derived via summing resistors R91 thru R93 and amplifier A9B is currently not used on the Polymoog. Either analog switch 1, 2 or 4 is turned on via a +15 VDC control signal from mode selector switch SW1 on the front panel. The selected gate feeds output resonator current to gain recovery amplifier A1B driving the front panel RES master gain control R2 via pin 5 of P82.

Eight master preset (MODE) filters are contained on eight separate boards which plug into the top center board. (Volume II.) Figure 5-1 illustrates the frequency response of these eight filters. String filter board No. 1 contains a high pass section comprised of C1 and R1 with a corner frequency of 80 Hz and is buffered by A1A driving a shelving filter comprised of R2, R3 and C2 with a corner frequency of 4.7 kHz. The shelving filter output drives amplifier A1B whose output is capacitively coupled to the final output on pin 6. Piano filter board No. 2 is comprised of two low pass sections with interstage buffering by A1B with a corner frequency for each filter of 60 Hz, followed by a gain of two amplifiers comprised of A1A, R2 and R3 driving a high pass section comprised of C3 and R5 with a corner frequency of 300 Hz. The high pass section output drives the sharp cutoff two pole filter with a corner frequency of 1 kHz comprised of A2A, A2B, R7, C5, R6 and C4. The output of the sharp cutoff filter on pin 7 of A2B drives a single low pass section with a corner frequency of 3.4 kHz. This low pass section is coupled to the output via C7. Organ filter board No. 3 is comprised of three band pass filter sections comprised of A1A, A2A, A2B and associated components. These three band pass filters are summed by A1B and are capacitively coupled to the output via C3. Harpsichord filter board No. 4 is comprised of a two stage shelving filter with a corner frequency of 3.0 kHz. Trim pot R4 allows for varying shelf height. This two stage filter drives another high pass section comprised of C3 and R6 with a corner frequency of 660 Hz and feeds drive amplifier A1B coupled to the output via C4. Funk filter board No. 5 is comprised of three band pass sections summed via A1B and capacitively coupled to the output via C3. Clavinet filter board No. 6 is also comprised of three band pass filters summed via A1B and capacitively coupled via C5 to the output. An additional direct feed occurs via the high pass section comprised of C1 and R1 and this coupling causes a notch at approximately 3.0 kHz. Vibes filter board No. 7 consists of a single band pass filter capacitively coupled to the output via C3. Brass filter board No. 8 is comprised of a single band pass filter capacitively coupled to the output via C3.

5.2 GENERAL SERVICING

The TC board contains three main audio paths: DIRECT, MODE and RESONATOR. An audio signal through these paths may be traced in a straight forward manner using an oscilloscope. Selection of a preset followed by depression of a note should cause an audio signal to appear from the appropriate mother board on pins 1 thru 3 of P83. The direct signal path consists of single amplifier A1A. The MODE filter signal is traced sequentially through IC1, A2A, A2B, A3A, gain compensation resistor networks N2 thru N4, input selector IC2, drive amplifier A4, output of the preset filters on pin 6 of the individual filter board connectors, output selector IC3 and finally to the voltage output on pin 3 of IC3.

> **NOTE**
>
> The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting and alignment procedures and after replacement of all malfunctioning parts.

FIGURE 5-1 POLYMOOG FREQUENCY RESPONSE OF FILTER BOARDS NO. 1 THRU 8 (TC BOARD 8)

5.3 ALIGNMENT

The only adjustment for the TC board is setting trim pot R4 on harpsichord filter board No. 4 to its mechanical center position or to desired position while listening to the harpsichord mode output.

5.4 REMOVAL

The TC board is hinged at the right edge and may be lifted up for bottom access by removing four screws at the left and center of the board.

5.5 TROUBLESHOOTING

Troubleshoot the TC board using Table 5-1, circuit description (paragraph 5.1), general servicing (paragraph 1.16), and parts location and schematic diagrams (Volume II). Note that voltage levels and waveforms displayed on the schematic diagram are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part.

TABLE 5-1
POLYMOOG TC BOARD 8 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
No DIRECT slide control R3 response	A1A, N1, mother board outputs
No MODE slide control R1 response	IC1, A2B, A2A, N1 thru N4, IC2, A4, Q2, IC3, Q1, master preset filter boards No. 1 thru 8, mother board outputs
No LOW, MED or HIGH resonator outputs or no RES slide control R2 response	IC4, A1B, IC1, A3A, A3B, C1, A2A, A2B
No low frequency (60 to 300 Hz) resonator output or no LOW GAIN, LOW EMPH or LOW CF slide control (R58 thru R60) response	A5A, A5B, A6A, N5, N8, N9, IC4, SW1
No medium frequency (300 to 1500 Hz) resonator output or no MED GAIN, MED EMPH or MED CF slide control (R68 thru R70) response	A7A, A7B, A6B, A9B, N6, N8, N9, IC4, SW1
No high frequency (1500 to 7500 Hz) resonator output or no HIGH GAIN, HIGH EMPH or HIGH CF slide control (R80 thru R82) response	A8A, A8B, A9A, N7, N8, N9, IC4, SW1

5.6 POLYMOOG KEYBOARD AUDIO CIRCUIT DESCRIPTION TC BOARD 8
(Reference Figure 5-2)

The AUDIO circuit board (TC board consisting of filter boards 1 and 2) in the Polymoog Keyboard combines and filters the audio outputs from the three MOTHER boards. All audio circuits on this board are referenced to a voltage rail derived from the +5 (Vcc) by AC bypasses to the rear panel AUD GND. This audio reference rail is labeled Vchr. The derivation of the audio rail is shown in the far right bottom of the schematic. The +5 VDC is bypassed with the RC network comprised of R53 and C17 and buffered by the voltage follower A5. The Vchr rail is applied to the low, medium and high mother boards and the front panel board in addition to serving as the on board audio reference rail. It should be noted that the outputs from the modulator cards on the mother board are differential currents which are converted to a single voltage drive referenced to this Vchr rail. Thus all audio in the system is referenced AC-wise to the rear panel ground, picked off at the J9 MAIN OUT rear panel connector.

The audio signals from the three MOTHER boards enter at connector P84 pins 4, 5, 6 and are summed for a composite audio signal via R1 through R4 and amplifier A1A. The output of this amplifier is the "direct output," applied via R5, C1 and connector P84 pin 1. This summed, direct signal is applied to two audio filter boards via S85-1 and S86-1 and to the voltage controlled filter via C4 and R30. The two filter boards contain fixed filters for ten of the presets. The voltage controlled filter is the audio path for presets 9 and 10 (BRASS). The audio outputs from the two filter boards and from the voltage controlled filter are applied to the filter selection analog switch selectors, IC1 and IC2, which select the appropriate filtered version for a particular preset. The inputs to these selectors are shown on the left hand side of the IC's. The audio outputs from these selector IC's are on pin 3 and feed the selected audio signal to the volume control circuit (SWELL circuit) via C2 and R17. The digital control signals for selecting the appropriate output from IC1 and IC2 are applied to pins 6, 9, 10 and 11.

When the BASS FILTER is activated from the front panel, the audio signal from the MOTHER board applied to the direct summer via P84-6 is defeated and instead the audio output from the lower two octaves is applied to the bass filter via P84 pin 2. This bass filter consists of amplifiers A3A and A3B and associated components. The output of the bass filter is applied to the front panel BASS LEVEL control (R55) via P83 pin 5 and is returned by switching networks on the front control board to pin P84 pin 7 which routes the bass filter signal to the SWELL control circuit via C5 and R18. Thus the

audio signal applied to the positive input of amplifier A1B is the sum of the selected filtered MOTHER board signals and the BASS FILTER, if it is active.

The BASS FILTER is comprised of resistors R37 through R43, amplifiers A3A and A3B, capacitors C11 and C12 and the associated front panel frequency control potentiometers R54A and R54B. The bass filter is a standard state variable circuit with a Q of 3 and frequency range of 60Hz to 300Hz. The SWELL control circuit is comprised of Q1, Q2, A1B, and associated components. The SWELL control signal, injected on the J7 SWELL rear panel connector, ranges from 0 to 5 VDC. This control signal is filtered with the network comprised of R15 and C3 and applied to the exponentiating circuit comprised of Q1, R16 and Q2 via the resistor divider R13 and R14. The exponentiating circuit is biased with the SWELL range control R11 which sets the bias point for Q1 and Q2. This circuit converts the control signal applied to the rear panel to an exponential current which drives the LED in the photocell circuit (PC1) via the current limit resistor R20. The photocell circuit attenuates the sum of the selected filtered audio signal and the bass filter via R21 and the cell resistor. When the LED is at maximum brightness, maximum attenuation occurs. This condition in turn occurs when 0 volts is applied to the J7 rear panel SWELL input connector. The SWELL range control R11 is set so that 1dB of attenuation occurs with no input applied to J7. Amplifier A1B is a voltage follower with a gain of 8. This amplifier drives the front panel VOLUME control R56 via R24 and P83 pin 1. The front panel attenuated signal is then coupled to the rear panel MAIN OUT connector via the 1.0 uf coupling capacitor (C1) located on the LHC (left hand control) printed circuit board 8.

The voltage controlled filter, used for presets 8 and 9, is driven from the direct signal via C4 and R30 presenting a RMS signal level of approximately 20mV to the base of Q11. The voltage control filter is comprised of Q3 through Q14, the output amplifier, the external cutoff frequency drive amplifier A4B and associated components. Filter contour signal is injected on P81 pin 7 and the keyboard drive signal is injected on P81 pin 8. These two signals and the external cutoff control signal injected via R50 are summed on the load resistor R49 along with the range control current provided by the RANGE trim pot R44 and the drive resistor R45 and applied to the base of the emitter follower Q14 and R48. This in turn drives the exponentiating transistor Q13 which acts as a current sink for the transistor ladder pairs comprised of Q3 through Q11. The audio signal injected at the base of Q11 traverses up the ladder and is filtered at each transistor stage with a cutoff frequency proportional to the standing current through the transistors. The differential signal appearing at the top of the ladder on the emitters of Q4 and Q3 is applied to the OTA gain recovery amplifier A2. This converts the low level audio signal at the top of the transistor ladder to an output voltage on pin 6 of A2 whose level depends on the bias current set by R32 and the output load resistor which is the parallel combination of R31 and R33. The output voltage signal is applied to the output preset selection gates in IC2 via C10. The range control is adjusted so that with 0 V applied to P81 pin 7 and VDC applied to P81 pin 8, the cutoff frequency of the filter is 200Hz. Frequency response of the filters is illustrated in Figure 5-2.

5.7 FILTER BOARD 1

Filter board 1 plugs into the top center board through connectors P86 and P87. This board contains six filters for presets No. 1, 4, 5, 6, 8, 11, 12 and 13.

Filter 1 (VOX HUMANA) is a simple highpass RC network comprised of R1 and R2 and a voltage follower, A1A. Resistors R1 and R2 can be used to gain scale the output. The cutoff frequency of this filter is 5.5kHz. Filter 4 (PIANO ELECT) consists of two stages. First, a two-stage lowpass filter comprised of A2A and associated components with a cutoff frequency of 1kHz followed by a single stage lowpass filter comprised of R6 and C4, followed by a second two-stage lowpass filter comprised of A2B and associated components with a cutoff frequency of 1kHz.

Filter 8 (HARPSICHORD), consists of two stages. The first stage is a filter with a shelf at 3kHz. The second stage is a high pass filter comprised of C21 and R44 followed by the buffer amplifier and the gain set resistor R45.

Filters 11 and 12, (PIPE ORGAN and ROCK ORGAN) use a common low pass filter section comprised of amplifier A3B and associated components. This low pass filter has a Q of 6 and a cutoff frequency of 7.2kHz and provides the rock organ signal via gain scaling resistors R21 and R22. This filtered output is added to that of a second low pass filter comprised of A3A and associated components. The

second filter has a Q of 4.3 and a cutoff frequency of 3.0kHz. The two filters outputs are added together in the buffer amplifier A4B via the feed resistors R14 and R16 and the gain scaling feedback resistor R15 to provide the pipe organ output on S87-5 pin 5.

Filter board 2 contains filters for the CLAVINET preset 7 and the FUNK preset 14. The CLAVINET filter consists of three bandpass sections. The first section comprised of amplifier A1A and associated components has a center frequency of 4.2kHz and a Q of 1.5. The second section, composed of amplifier A1B and associated components, has a cutoff frequency of 335Hz and a Q of 2. The third section, consisting of amplifier A2A and associated components, has a cutoff frequency of 80Hz and a Q of 2. A fourth high pass section, consisting of C3 and R4 with a cutoff frequency of 225Hz, is combined with the outputs of the three band pass filters in amplifier A2B and the output scaling resistor R7.

The FUNK filter has three band pass sections associated with amplifiers A3A, A3B, and A4A. The first band pass filter associated with A3A has a cutoff frequency of 150Hz and a Q of 1.6. The second band pass filter associated with A3B has a cutoff frequency of 1.6kHz and a Q of 1.8. The third band pass filter associated with A4A has a cutoff frequency of 3.1kHz and a Q of 1.6. The outputs from these three band pass filters are combined in amplifier A4B and the output scaling resistor R26.

5.8 POLYMOOG KEYBOARD VOX HUMANA FILTER BOARD 14

This filter is comprised of three low pass filter sections associated with amplifiers A1A, A2A, A2B, respectively. The outputs from these three filter sections are summed via R5, R12, and R17 in the output amplifier A1B whose feedback resistor R6 determines the overall filter gain.

The first filter associated with A1A has a cutoff frequency of 1750Hz and a Q of 11. The second filter associated with A2A has a cutoff frequency of 330Hz and a Q of 2. The third filter associated with A2B has a cutoff frequency of 1600Hz and a Q of 1.

5.9 AUDIO CIRCUIT ALIGNMENT

5.9.1 VCF CUTOFF FREQUENCY

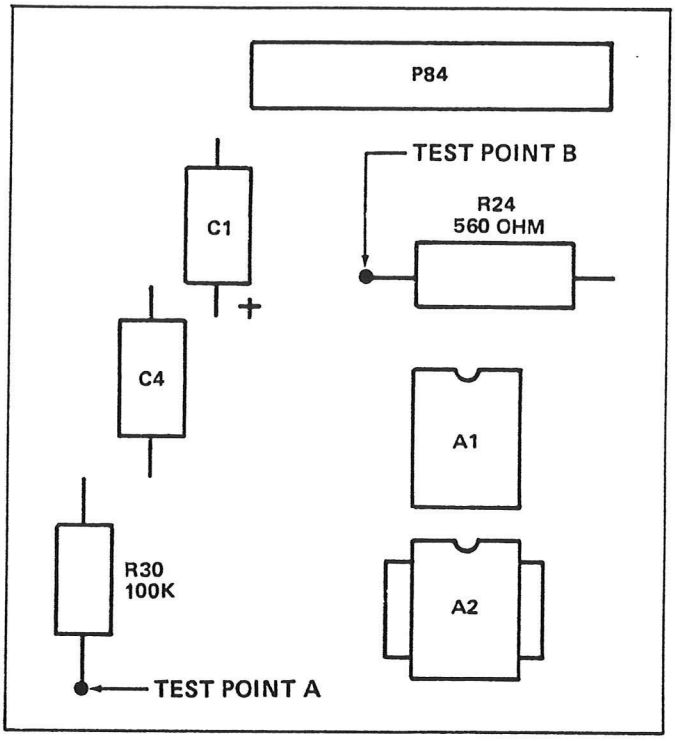
a. Depress preset No. 9.

b. Connect P81-7 to ground.

c. Connect P81-8 to +5VDC.

d. Place filter into oscillation by connecting a series 0.33uf precision capacitor and a 10K ohm ± 1% resistor from P83-1 to pin 2 of IC3. Refer to sketch, points A and B respectively.

e. Adjust R44 for 200Hz at main output.

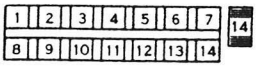


PART OF AUDIO CIRCUIT BOARD

5.9.2 SWELL RANGE

a. Depress preset No. 9.

b. Depress A_4 and adjust trimpot R11 for maximum output; then slowly back off R11 until main output drops 1.0dB from full output. (10% drop in amplitude). Insert shorting plug in rear panel SWELL jack and observe reduction in output level of 30dB ± 3dB. Remove shorting plug.



5.10 KEYBOARD DISASSEMBLY

a. Disconnect power cord connector and all other rear panel connections.

b. Remove four screws securing cover to rear panel extrusion using a medium sized Phillips head screwdriver.

c. Loosen two captive knurled thumb screws under the instrument extreme front left and right sides until they turn freely and lift cover directly up.

d. Reconnect power cable and audio signal monitor.

e. All internal alignment and adjustment controls are now accessible.

5.11 TROUBLESHOOTING

Troubleshoot the audio circuit board using Table 5-13, printed circuit description paragraph 5.6, and parts location and the schematic diagrams in Volume II.

TABLE 5-13
POLYMOOG KEYBOARD AUDIO TC BOARD 8 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
No output in any preset	A1A, A1B, IC1, IC2
Voices with no filter effect	IC1, IC2, IC3, A2
Filter inoperative	IC3, Q5, Q6, Q7, Q8, Q9, Q10, R44 out of Calibration
Filter cutoff using pedal	A4B, Q14
Swell pedal has not effect	Q1, Q2
No bass filter output or cutoff	A4A, A3A, A3B, R54A, R54B, R55, C11, C12
No output from main output jack	IC1, IC2, A1B, R56
Some preset voices out	Filter Board IC1, IC2

SECTION 6
BOARD 9
POLYMOOG VOLTAGE CONTROLLED FILTER AND KEYBOARD CIRCUIT AND POLYMOOG KEYBOARD PROGRAM CONTROL
TR

6.1 CIRCUIT DESCRIPTION - POLYMOOG

The voltage controlled filter and keyboard circuit printed circuit board assembly (TR) contains the following major sections: (1) trigger and monophonic keyboard circuits; (2) voltage controlled filter and associated circuitry; (3) brightness drive; (4) modulation oscillator and (5) output summing and drive circuitry. (See Volume II).

The upper left section of board 9 schematic (Volume II) contains a digital control logic section associated with VCF ON-OFF switching, FOOT SUSTAIN, LOWER-UPPER VCF switching and external trigger. When SVOO line is logic "O", the VCF is OFF forcing the outputs of G4 and G5 high and G8 and G9 low, turning off the audio feed signal from the mother boards via the FET gates and IC12. In addition, the output of G6 is forced high, forcing the output of G10 low (if no external trigger is applied to the CSTI line via CR2) holding down the reset line on the LM555 (IC5) and also holding the trigger line to IC5 high, because transistor Q3 is turned on via R57 to prevent the VCF contour generator from triggering when the VCF is off.

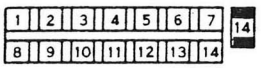
When the SVOO line is logic "1," gates G4, G5 and G6 are enabled permitting these gates to be controlled from the UPPER/LOWER switching line (SKL), ALL-SPLIT line (SKTM) and the internal trigger signal to G6 via R7. If the SKTM signal is a logic "0" (ALL mode), G1 is forced high, forcing G5 low and allowing SVCL, the low keyboard audio feed line, to be applied to the VCF. This ALL mode forces the SKL line to a logic "1" via a coupling on the control board, which causes the SVCH signal, the control line for the audio signal from the high mother board, to go high. If the SKTM line is a logic "1," gates G8 and G9 are controlled via G1, G4 and G5 and are in opposition, that is, either the SVCH or the SVCL line is a logic "1" under control of the SKL, the UPPER/LOWER switching signal.

Whenever the VCF is on, the SVOO line enables G6, permitting a trigger signal to be applied to G10 and subsequently to IC5 via R57.

When a key is depressed on the portion of the keyboard selected by the SKL line, the output of A5B goes positive. This d-c trigger is applied to G10, the drive for the VCF contour generator, and G12, the external trigger gate. The external trigger gate is enabled via the KCEX line, the external input trigger control line.

An a-c trigger is developed by amplifier A4B and consists of a negative going 5 millisecond pulse which is coupled to external S-trigger gate G12 via R28 and CR6. The d-c trigger signal from A5B initially causes G12 to go negative. Subsequent retriggers from A4B cause G12 to open for the 5 millisecond pulse duration. The open collector output of G12 (IC3) is paralleled with the open collector output of G13 (IC9), the single/multiple trigger control gate. The d-c trigger signal from A5B is also applied to G13 via R89. If the single/multiple trigger control KTSM is logic "0," the instrument is in the multiple trigger mode and gate G13 is disabled via R88 and CR13. If the instrument is in the single trigger mode, the KTSM line is positive and gate G13 is enabled. Therefore in the single trigger mode, the d-c trigger from A5B via G13 overrides any multiple triggering effect from G12 for the external S-trigger. The effect of G13 is further disabled when the external keyboard control is in the off mode via the ESOO line and CR12. The ESOO line is paralleled with the KCEX line and also defeats S-trigger action via gate G12.

Single/multiple trigger control of the VCF contour generator is accomplished via G14 in IC9. When the instrument is in the single trigger mode, namely, KTSM = "1," G14 is enabled to respond to the d-c trigger from A5B. When a d-c trigger occurs, the output of G14 goes negative turning on transistor Q3 via R94. However, there is a delay introduced via the RC network comprised of R93 and C48 so that the



initial a-c trigger can be applied to IC5 from A4B through R28 and R58, before the d-c trigger turns on Q3.

Foot sustain (final decay control) is accomplished via the SFTEX or SVFTO lines. If either of these lines is a logic "0," the outputs of G2 and G3 are forced high. When G3 goes high, current is provided to the emitter of Q1 via R10 causing the FTSUBL, M and H lines to go from -5.5 to approximately 0 VDC causing final decay to occur on all modulators on each mother board. When final decay is on, the output of G2 is high causing the output of G7 to be low forcing the output of G11 high. This high output causes CR20 to be reverse biased and allows contour generator integrating capacitor C21 to operate (go positive). When the final decay is off, caused by both SFTEX and SVFTO lines being positive, G11 is disabled via G7. The output of G11 is controlled via the input on pin 1 of IC2 which is coupled to trigger control gate G6 via CR1. Whenever a key is depressed with the VCF ON, the output of G6 goes negative, causing the output of G11 to go positive, again allowing voltage to rise on contour capacitor C21. When no key is depressed and both SFTEX and SVFTO lines are logic "1" (off), the output of G11 is pulled to ground and the voltage across contour capacitor C21 is pulled to ground with a 10 milliseconds time constant via CR20 and R72. Thus, final decay control operates on both mother board modulator circuits and the filter contour generator simultaneously.

Whenever a key is depressed, a (minimum) current of 4 microamperes is applied to either trigger buss line TRGL or TRGH from the lower and upper keyboard sections, respectively. These currents are routed through FET current switches contained in IC7 and IC8 under control of the LOWER/UPPER control line, SKH. Either one or the other, or both, of these FETs are on depending upon whether the keyboard is in the UPPER, LOWER or ALL mode. When the VCF is in the ALL mode, the FET in IC8 is turned on via the inverter in IC7 and R34. In addition, the FET current switch in IC7 is turned on via gate G15 whose open collector resistor pulls up the base of Q25 (via reverse emitter base breakdown) to turn on the switch. If the VCF is in the SPLIT mode, then LOWER/UPPER trigger current switching is accomplished via the P channel inverter in IC7 and the subsequent inverter (also in IC7) comprised of the P and N channel FETs.

The selected trigger currents are routed to summing amplifier A5A which generates a (minimum) negative step of approximately 200 millivolts each time a new key is depressed. The output of A5A drives comparator A5B whose threshold is approximately 200 millivolts below the zero trigger signal output reference of A5A. Depression of one or more keys causes the output of A5B to swing from -15 to approximately 3.5 volts. This d-c trigger is applied to trigger control gate G6, external S-trigger gate G12 and single/multiple control gates G13 and G14. The d-c trigger enables the reset input of IC5 via R7, control gate G6 and AND gate G10.

The output of trigger summing amplifier A5A is coupled via C4 and R24 to a-c trigger generator A4B. In addition, the external trigger input on the CSTI line is coupled to this a-c trigger generator via C3 and R23. The positive input of A4B is biased to the -5.5 VDC rail via R25 and R24. The minus input reference is approximately 200 millivolts more negative, derived from divider resistors R15 and R16. Each time a key is depressed, a step waveform on A5A causes a 5 millisecond negative going pulse on A4B. A small amount of regeneration providing Schmitt trigger action is accomplished via R29 and C7. The a-c trigger output of A4B is coupled to trigger buffer amplifier A4A to provide a monophonic keyboard sample and hold pulse, to the contour generator via R28 and R58 and to the external S-trigger gate G12 via R28 and CR6. CR5 clamps the trigger applied to the contour generator and S-trigger gate G12 to ground.

The d-c trigger from A5B is also coupled via R18 to the STRING PRESET No. 1 contour generator comprised of A6A and B and associated components. A d-c trigger causes the output of A6A to rise to +13.5 VDC generating a contour with a rise time of 100 milliseconds, a fall time of 560 milliseconds and an amplitude of 13.5 volts to occur on the MACG line used to contour the amount of frequency and pulse width modulation when the instrument is in the string mode.

The VCF contour generator is comprised of IC5 A11, A12, A13, A10B, A10A, IC6, Q4, Q3 and associated components. This contour generator has current controlled attack time, decay time and sustain level. These currents enter on the PCATN, PCDEN and PCSUN lines, respectively. The sustain current generates a sustain level voltage on the output of A10B; the larger the sustain current, the lower the sustain level.

IC5 generates an internal control voltage of 10.0 VDC on pin 5. When IC5 is triggered, the output at pin 3 rises to 13.5 VDC and stays at this voltage until the threshold control voltage at pin 6 rises above the control voltage on pin 5. At this time, the output of IC5 resets to ground potential. Thus, when a note is depressed, IC5 is triggered and its output goes to 13.5 volts enabling gates C2 and C3 in IC6. Gate C2 is used as an inverter via R73 which drives gates C4 and C3 in opposition. In addition, gate C1 is enabled as long as any key is depressed.

The maximum output of sustain amplifier A10B is 11.0 volts. Assume A10B output is about 5.7 volts. When IC5 output goes to 13.5 volts, the voltage at the junction of R61 and R62 rises to 10 VDC and CR18 is reverse biased. During attack time, gate C3 in IC6 applies attack current on the PCATN line and to the current-level-converter section comprised of A10A, Q4 and R69. This attack current is applied to the negative input of A10A causing the output of A10A to go sufficiently negative so that current flowing through R69 is equal to the attack current. This attack current is applied to pin 5 of A11 (CA3080) via the collector of Q4. In addition, a small amount of current is provided to pin 5 of the CA3080 (A11) via R68. Trim pot R70 and resistor R71 shunt part of this current provided by R68. Trim pot R70 is adjusted so when zero current is provided to the PCATN line (longest attack and decay), 1 microampere of current is delivered to the output from pin 6 of the CA3080 during attack and decay phases, providing 10 second attack and decay times.

A 10 volt signal at the junction of R61 and R62 is divided down by R62 and R67 and applied to pin 3 (the positive input) of A11. Assume the output of A11 (pin 6) attached to integrating capacitor C21 is initially at zero. The output of A12, a high input impedance buffer follower, is zero and voltage applied to a resistor divider comprised of trim pot R64, and resistors R65 and R66 and to the threshold input at pin 6 of IC5, is zero. The output at pin 6 of A11 will begin to rise at a rate determined by the current supplied by Q4 and the capacitance of C21. As this voltage rises, so does the output of A12 and thereby the feedback voltage applied to the negative input of A11 via trim pot R64 and resistors R65 and R66. The output of A11 will continue to rise until voltage on the negative and positive terminals are equal and contour generator feedback trim pot R64 is adjusted so that this occurs when the voltage at the output of A12 is equal to the voltage at the junction of R61 and R62, namely, 10 volts during the attack phase. This feedback voltage from A12 is also applied to the threshold input at pin 6 of IC5 via R63. When this threshold voltage reaches 10 volts, the output of IC5 goes to zero. Diode CR16 is used to prevent the condition of simultaneous triggering and resetting on IC5 which might cause it to burst at high frequency. When the output at pin 3 of IC5 goes to zero, gates C2 and C3 of IC6 are disabled and gate C4 is enabled applying decay current on the PCDEN line to the current level translator (A10A and Q4) described previously. As mentioned previously, the sustain level voltage at the output of A10B is applied thru IC5 to R61 and R62 via CR15. Since the output at pin 3 of IC5 has now gone negative, voltage at the junction of R61 and R62 is equal to the output voltage of A10B of the sustain level controller minus a diode drop, which would be about 5.0 VDC according to our previous assumptions. The new "equilibrium" point for the output of A11 will be 5 volts instead of 10 volts as it was during the attack phase.

The CA3080 A11 now seeks this new equilibrium point at a rate determined by the bias current injected on pin 5 which is now the decay current. As long as any note is held, gate 1 of IC6 is open and CR20 is reverse biased and once this new equilibrium voltage is reached, it remains there. When all keys are released, one of two things occur depending on whether FINAL DECAY is on or off. If FINAL DECAY is on when all keys are released, gate 1 of IC6 closes and voltage applied to A11 via R62 drops to zero. In this case, the new equilibrium point for the output of A11 is zero and it seeks this new point at a rate determined by the decay current. As mentioned previously, final DECAY on implies that CR20 is reverse biased. If, for example, all keys are released and final decay is off, gate C1 is closed and the anode side of CR20 drops to zero rapidly pulling down the voltage across C21 from whatever sustain level was held while the keys were being depressed.

Contour generator feedback trim pot R64 is adjusted so the output of A12 goes to 11 volts with minimum attack and decay current, assuring that feedback voltage will reach 10.0 volts, the value required to reset IC5, and proceed to the contour sustain phase.

The buffered output of the VCF contour generator (pin 6 of A12) is applied to A13, the contour amount VCA via resistor divider R75 thru R78 to provide a voltage drive level proper for linear VCA action. Contour generator amount balance trim pot

R76 is set so that with bias current applied to pin 5 of A13, this contour amount VCA provides a current equal to the product of the divided down contour voltage and the contour amount current on the PCAMN line. Transistor Q10 provides a low impedance summing point for currents on the PCAMN line and translates this current to VCA A13 by its collector. The output current of contour amount VCA A13 is summed along with the modulation amount current from A9, the sample and hold amount current from A8 and VCF cutoff current at load resistor R83. This sum is applied to VCF current source Q11 and Q12 and is described later.

The VCF section contains a modulation oscillator comprised of A1, A2B and A3B which generates a triangular wave and a square wave. The triangular wave is used to modulate the cutoff frequency of the filter via a VCA and the square wave output is used to trigger a sample and hold circuit which samples a random noise source. The resulting random step pattern is applied to the cutoff frequency of the voltage controlled filter via a VCA.

Current controlling the modulation rate of the modulation oscillator is injected on the PVMRN line. This current is transferred to the bias input (pin 5) of A1 via a current translation circuit comprised of A2A, Q2 and R22. An additional fixed current of 1.5 microamperes is provided to this bias input via R26. A1 acts as a switched current source with bias current applied to pin 5 appearing at output pin 6 with a polarity determined by the input drive to pin 3. A2B is a high impedance follower driving a Schmitt trigger comprised of A3B, R30 and R27. The output of A3B is either fully negative or fully positive, that is, plus or minus 14 volts and sets a positive and negative threshold of approximately 2.5 volts on the positive input (pin 5) of A3B. At the same time, this threshold is used to switch the current polarity of A1. The current output of A1 causes the voltage to rise linearly on C1 and on the output of A2B until it reaches a value of +2.5 volts. At this time the output of A3B switches negative setting a threshold of -2.5 volts and also switching the current direction on the output of A1, reversing the voltage range. This action results in a triangular wave output at pin 7 of A2B of approximately 5 volts peak-to-peak which is applied to the modulation amount voltage controlled amplifier comprised of A9, R53, R54 and C20. Gain control of this VCA is accomplished via current injected on the PVMAN line. Transistor Q6 acts as a current level translator for the bias input to A9 and the modulation amount VCA current output of A9 is applied to the cutoff frequency summing node described previously.

The 28 volt peak-to-peak square wave is applied to the differentiating network comprised of C16 and R45 to provide a current pulse to sample and hold amplifier A7. This current pulse turns on amplifier A7 at which time sample and hold capacitor C17 is charged by the output current from pin 6 of A7 to a voltage such that the voltage appearing at the source of FET follower Q7 provides feedback current via R44 to satisfy conventional closed loop operational amplifier operation. Random noise source IC4 generates a random sequence of 13 volt pulses. A bypass network comprised of R40 and C13 prevents "hash" from occurring on the supply line to pin 4 of IC4. The output of the random noise source on pin 3 is a-c coupled via C14 and lowpass filtered via R42 and C15 and applied to the negative input node of A7 via R43. Thus, during the brief sampling period, a current which varies from sample to sample is fed to the summing node of A7 and the sampling pulse "closes the loop" for a brief interval. The result is a random step function on the output of source follower Q7 which is lowpass filtered to eliminate short overshoots via R48 and C18 and applied to the negative input at pin 2 of sample and hold amount VCA A8 via voltage divider network R49 and R50. Gain control of this sample and hold amount VCA is accomplished via current on the PVSHN line where Q5 acts as a current level translator to pin 5.

The monophonic keyboard system for external keyboard drive and for VCF keyboard drive is comprised of part of IC7, A14A, A14B, IC10, IC11, A15, A16, A17A, Q9 and associated components.

The monophonic section keyboard contains two independent resistor strings for the lower two octaves and upper four octaves. Each resistor in the string is 100 ohms and the total resistance for the lower string is 2400 ohms while total resistance for the top string is 4700 ohms. When a key is depressed, a switch connects a point on the resistor divider string to keyboard buss KBBS, common to both keyboard sections. A keyboard voltage is derived from either the lower or upper resistor string, but not both simultaneously. This is accomplished by applying a constant current source to either the upper or lower resistor string, but not both simultaneously. For example, if the upper string has current applied, the lower string is

floating between reverse bias diodes. Figure 6-1 is a simplified drawing of this keyboard circuit showing the resistor strings. The FET switches in IC7 and IC8 apply a precision positive potential or an adjustable precision negative potential to R98 and R99. Voltage conditions shown are for application of current to the upper keyboard string. The 0.5 milliampere current drawn through R98 and R99 causes a current of equal magnitude to be drawn down through R_u', a dummy upper keyboard string. If R_u' is equal to R_u and if the drops across diodes CR1 and CR1' are equal (true because both are carrying equal current and they are well matched diodes contained in a single integrated circuit package) and if R102 and R105 are well matched resistors, the high open loop gain of A14B will force the lower end of the upper keyboard resistor string, R_u to be precisely at 0.0 volt. If a section of the keyboard resistor string is shorted by depression of more than one note on the upper keyboard string, the upper potential of 2.35 VDC will remain constant since the lower leg of the circuitry attached to the plus input of A14B is an independent fixed feedback loop for A14A and applies 2.35 VDC to the lower resistor string. A similiar condition exists when a positive potential is applied to R98 and R99. It should be noted when the upper keyboard resistor string is carrying current, diodes CR2 and CR4 are reverse biased and the lower keyboard resistor string R_l is isolated from the upper keyboard string. Depression of a key on the lower part of the keyboard attaches some point on the R_l string to the keyboard buss and will not interfere or cause current to be drawn through the buss from the upper keyboard resistor string. Trim pots R100 and R103 provide a means of setting the lower voltage on the upper keyboard string precisely to the same voltage so that keyboard voltage is a continuous signal through the break in the keyboard sections. In addition these pots may be used to range the keyboard output voltage to drive a Minimoog or Micromoog.

When a key is depressed, a particular point on either the upper or lower keyboard strings is connected to keyboard buss KBBS. Simultaneously, a 5 millisecond positive going trigger pulse is developed and presented to gate 1 of IC11 (C1 line) opening the gate and storing the appropriate keyboard voltage across output capacitor C25. The keyboard voltage stored in capacitor C25 is buffered by high impedance amplifier A15 having an open loop gain of approximately 200 determined by R111, R107 and R108. A second feedback loop to achieve an approximate gain of two is accomplished via A16 and A17A. Whenever a new keyboard signal is acquired that is different from a previous value, the output of A15 switches current amplifier A16 via R112 and R113 causing the potential on glide capacitor C28 to slew in the proper direction so that the loop conditions comprised of A15, A16 and A17A are satisfied. The slew rate on glide capacitor C28

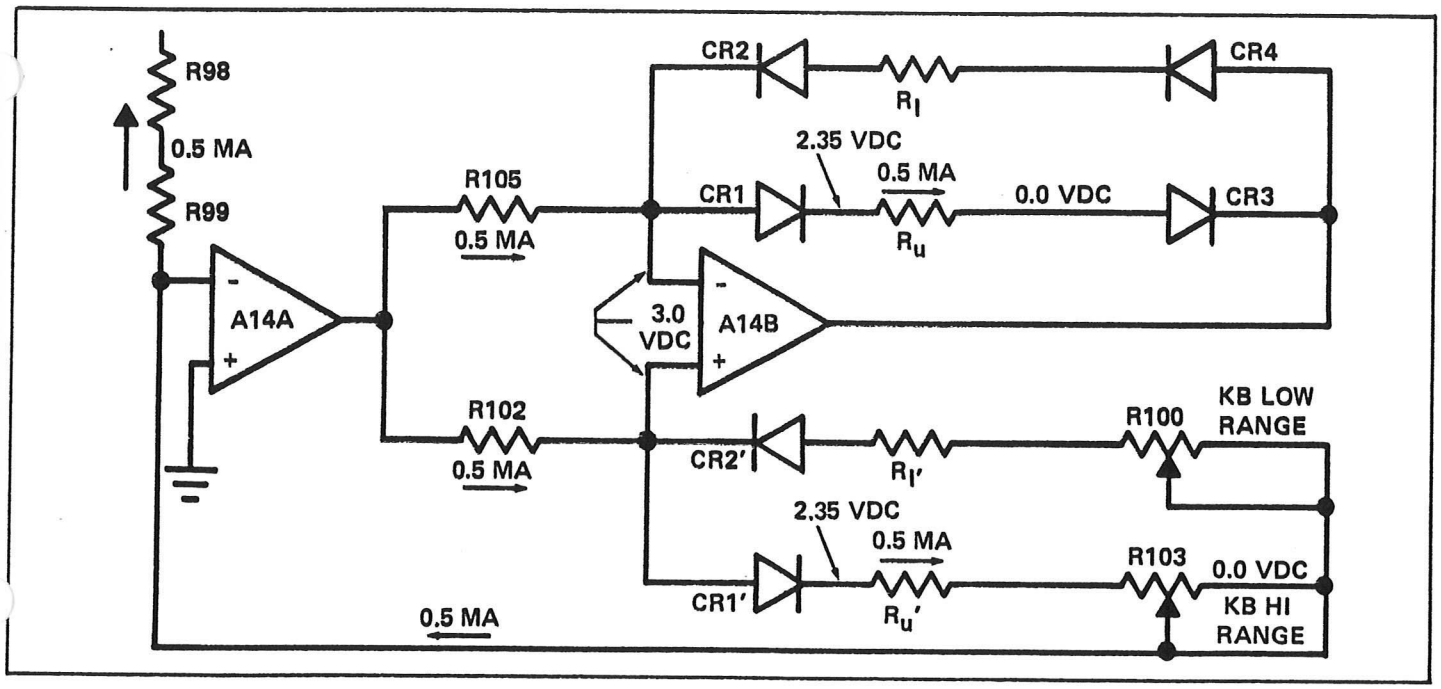


FIGURE 6-1 KEYBOARD CIRCUIT SIMPLIFIED DIAGRAM

is determined by the glide current introduced on the PKGLN line and transferred to the CA3080, A16, via current translation transistor Q9. R115 provides a minimum glide current of approximately 0.5 microampere. Amplifier A17A is a high impedance buffer amplifier providing drive to R107 and to the negative input of A15 closing the large feedback loop. Closure of the feedback loops around A17A and around the large feedback loop are accomplished via gate C2 of IC11 or via gates C3 and C4 of IC11. The external keyboard control KCEX line determines whether the C2 line or C4 and C3 control lines in IC11 are positive via the level translating and inverting gate contained in IC8. When the C2 line is positive, gate C2 is turned on, thereby serving as the feedback closure to R107. In this case, gates connected to outputs O_3 and O_4 are open and the external keyboard drive signal buss KBEX is open circuited. When gate C2 line is negative, C3 and C4 are positive applying the keyboard control voltage to the KBEX line from A17A via gate O_3 in IC11. Gate C4 serves as an isolated feedback return point to R107. This isolated return eliminates offsets due to the on resistance of the FET gates in IC11 when driving low impedance external loads. The rear panel KB SCALE variable resistor is connected between ground and the KBSC line and varies the overall loop gain between the voltage stored on sample and hold capacitor C25 and the keyboard output voltage on the KBEX line. However, variation of the rear panel KB SCALE variable resistor does not vary the voltage on the negative input of buffer amplifier A15, the point where the internal keyboard voltage drive to the VCF is derived. This internal keyboard voltage is applied to keyboard amount VCA A21 via divider network R175 and R174. Keyboard amount balance trim pot R172 provides VCA offset cancellation for the keyboard amount VCA. Current gain of keyboard amount VCA A21 is accomplished via level translator transistor Q17 and the N channel FET connected to pin 4 of IC14. Currently, control line SVVP is grounded turning on the N channel FET. This SVVP line is used to provide VAR-PRE control of glide current and is not currently used in the Polymoog. The output current of VCA A21 is applied to cutoff frequency summing load resistor R83 along with the previously mentioned contour amount current.

Audio inputs from the low, medium and high other boards enter the VCF board on the OUTLW, OUTMW and OUTHW lines. Gates C3 and C4 of IC12 selectively gate the audio signals from the lower, upper or both keyboard sections to gain recovery amplifier A18A, which simultaneously drives preset gain selector resistors R141 through R148 and preset drive resistor R149. The audio signal now passes through either a preset gain resistor or preset drive resistor R149, determined by the control signal on the SVVP line. Transistor Q13 is a level translator providing a 15 volt switching level activating either gate C2 in IC12 or one of eight gates in IC13. If for example, the collector of Q13 is a logic "0," one of the gates determined by encoded preset selection lines SPB1, SPB2 and SPB3 is turned on routing the signal to pin 3 of IC13 and to the audio input of the filter via C35. If the collector of Q13 is high, all gates in IC13 are inhibited and gate 2 in IC12 is on, applying audio input to the filter via R149 and C35. The VCF input level on pin 2 of IC15 is approximately 20 millivolts rms. The VCF in the Polymoog is the patented Moog filter using a pair of push-pull transistor ladders comprised of Q18 through Q23 and four transistors in IC15.

Transistor Q11 is an emitter follower for the composite cutoff frequency control signal and Q12 controls a current to the exponential current converter. This exponential current is applied to the double transistor ladder and, as collector current through Q12 is varied, the dynamic base emitter resistances of the transistors in the ladder vary in a tracking manner and, in conjunction with capacitors C36 through C39, provide a variable cutoff frequency. The differential output voltages from the top of the ladder, pins 7 and 10 of IC15, are applied to high impedance dual FET follower Q14 which drives two gain recovery amplifiers (CA3080s) A22 and A19. Gain recovery amplifier A22 provides feedback control to the transistor ladder. Emphasis amount trim pot R161 adjusts the amount of feedback voltage applied to pin 4 of IC15. Bias current injected onto pin 5 of A22 via the PVEMN line controls the amount of feedback and determines the emphasis or Q of the VCF. VCF ladder balance trim pot R166 is used to balance out offsets of FET follower Q14 and emphasis gain recovery amplifier A22.

Amplifier A19 serves as the main audio gain recovery amplifier. VCF level balance trim pot R162 is used to cancel any voltage offset of gain recovery amplifier A19. The output current of A19 is applied to current-to-voltage converter amplifier A20A which drives the direct VCF output via R168, C41 and the VCFO line. In addition, converter amplifier A20A drives output mixer amplifier A20B via R125.

The main gain recovery amplifier for VCF A19 is squelched whenever the VCF is turned off via diode CR25. Gain control of the VCF is accomplished by varying bias current to gain recovery amplifier A19 via resistor R181 and front panel MASTER GAIN VCF control R179.

The output mixer and swell circuits are comprised of Q15, Q16, PC1, A20B, T1 and associated components. The output mixer is a simple follower with a gain circuit summing the RES, VCF, DIRECT, MODE and AUX control input signals.

The composite voltage signal appearing at pin 5 of A20B is attenuated to a variable degree by the photoresistor contained in PC1. The resistance of this photocell is varied by the light intensity from the LED in PC1 which is in turn driven by a variable current source comprised of Q15, Q16 and associated components. If no signal is applied to the SWELL line, a bias voltage is applied to the base of emitter follower transistor Q15 via swell range trim pot R116 and divider resistors R117 and R118 such that current source transistor Q16 is just barely turned on. Swell range trim pot R116 is set so the signal level at pin 5 of A20B is attenuated 1dB below signal level when current source Q16 is turned fully off. If a voltage in the range of 0 to 5 volts is applied to the SWELL input, a variable current is passed to the LED in PC1 causing a variable attenuation of the signal level at the output of mixer amplifier A20B. Amplifier A20B drives 600 ohm output transformer T1 whose outputs are routed to rear panel XLR BAL MIX connector and a 1/4 inch phone jack.

Brightness control of the mother board modulators is accomplished via amplifier A3A and associated components. The output of A3A is 1.8 VDC when no current is injected on the PBRIN line, the brightness current control line from the front panel. Maximum brightness occurs when the output of A3A is -10 VDC.

6.2 GENERAL SERVICING

If the voltage controlled filter is completely dead, a simple audio tracing procedure can be used to locate the origin of difficulty. The audio signal (Refer to Volume II) enters on pins 2, 3 and 4 of J97, and via IC12, to gain recovery amplifier A20A and to coupling capacitor C35 either via IC13 or gate O_2 in IC12. The signal at C35 is a nominal 20mV maximum, so that observations must be made with a sensitive oscilloscope. An audio signal is injected into the transistor ladder at pin 2 of IC15 and exists from the transistor ladder on pins 7 and 10 of IC15 and connects to dual FET follower Q14. Low level audio may be viewed conveniently on Q14. The differential audio signal from Q14 is applied to gain recovery amplifier A19, filter output amplifier A20A and rear panel filter output and mix amplifier A20B. It is recommended that preset No. 8 be used with a key depressed to inject a signal into the voltage controlled filter. A determination of the components or part causing the problem can usually be accomplished by going through the above path and noting where loss of signal occurs.

Failures in individual circuit sections driving the filter should be located using the circuit schematic. The most sensitive components in these circuits are the CA3080s and CMOS ICs, namely: ICs 6 thru 8 and 11 thru 14. All CA3080s and CMOS ICs are plug in for easy replacement.

Difficulties with logic sections can usually be isolated by noting the appropriate output for related inputs to particular logic gates.

Should a power supply short occur, the difficulty (if it is a defective circuit element) can usually be noted by touching various ICs and transistors with the finger to see if they are warm.

> **NOTE**
> The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting and alignment procedures and after replacement of all malfunctioning parts.

6.3 ALIGNMENT - POLYMOOG

All trim adjustments for the top right board (Figure 6-2) are available by removing the top cover.

Monitor external output with a DVM and MIX output with a scope, monitor, and an AC voltmeter. Turn rear panel SCALE pot full counterclockwise (viewed from the rear) and VCF MASTER GAIN full up.

6.3 ALIGNMENT - POLYMOOG (Continued)

a. KEYBOARD LOW ADJUST

1. Depress "VCF Keyboard Split/Lower." Repeatedly depress Eb_2 and adjust R100 for -167mV. Repeatedly depress F_1 and adjust rear panel scale for -2.00V.

2. Repeat step 1.

b. KEYBOARD HIGH ADJUST

1. Depress "VCF Keyboard All." Repeatedly depress E_3 and adjust R103 for -83 mV.

2. Repeatedly depress F_6 and adjust R36 for +3.00V. Repeat steps 1 and 2.

> **NOTE**
> Refer to paragraph 1.23, Section 1 of this manual for alignment procedures to match the Polymoog Synthesizer control voltage output to that of another synthesizer.

c. CONTOUR GENERATOR FEEDBACK ADJUSTMENT

1. Depress voltage controlled filter VAR pushbutton and position CONTOUR ATTACK and DECAY slide controls full up and SUSTAIN slide control full down.

2. Depress KEYBOARD ALL pushbutton and short pin 6 of IC5 (anode of CR16) to ground. Connect DVM to pin 6 of A12.

3. Depress a key and adjust trim pot R64 for a voltage indication of 11.0 ± 0.1 VDC. Disconnect short and voltmeter after settling to steady state.

d. MAXIMUM ATTACK AND DECAY ADJUSTMENT

1. Depress VCF VAR and position all VCF pots full down except ATTACK full up, EMPHASIS full up and CONTOUR AMT one half up.

2. Observe waveform at pin 6 of A12 and adjust trim pot R70 for an attack time of 10 ± 1 seconds or by timing with a watch and listening to the VCF output.

e. CONTOUR GENERATOR AMOUNT BALANCE ADJUSTMENT

1. Short pin 7 of P93 to ground and connect DVM to pin 6 of A13.

2. In preset No. 6 adjust trim pot R76 for a voltage indication of 0.0 ± 0.010 VDC with no keys depressed. Disconnect short and DVM.

f. KEYBOARD AMOUNT BALANCE ADJUSTMENT

1. Depress voltage controlled filter VAR pushbutton and position all slide controls full down.

2. Short pin 2 of A15 to ground and connect DVM to pin 6 of A21.

3. Adjust trim pot R172 so that voltage indication is the same within ± 0.005 VDC with KB slide control full up or full down. Disconnect short and voltmeter.

g. VCF RANGE

1. Depress VCF VAR and place all VCF controls at full down except place EMPHASIS full up.

2. Turn R161 full counterclockwise (clockwise if using blue or metal trim pots) and observe that the filter activates.

3. Adjust R80 so that oscillator frequency is 60 ± 2Hz.

h. VCF LADDER BALANCE

1. Depress VCF VAR and place all VCF sliders full down except place CUTOFF one half up and EMPHASIS full up.

2. Connect DVM to pin 1 of A20 and turn R161 until filter oscillates, then turn back until oscillator just barely dies out.

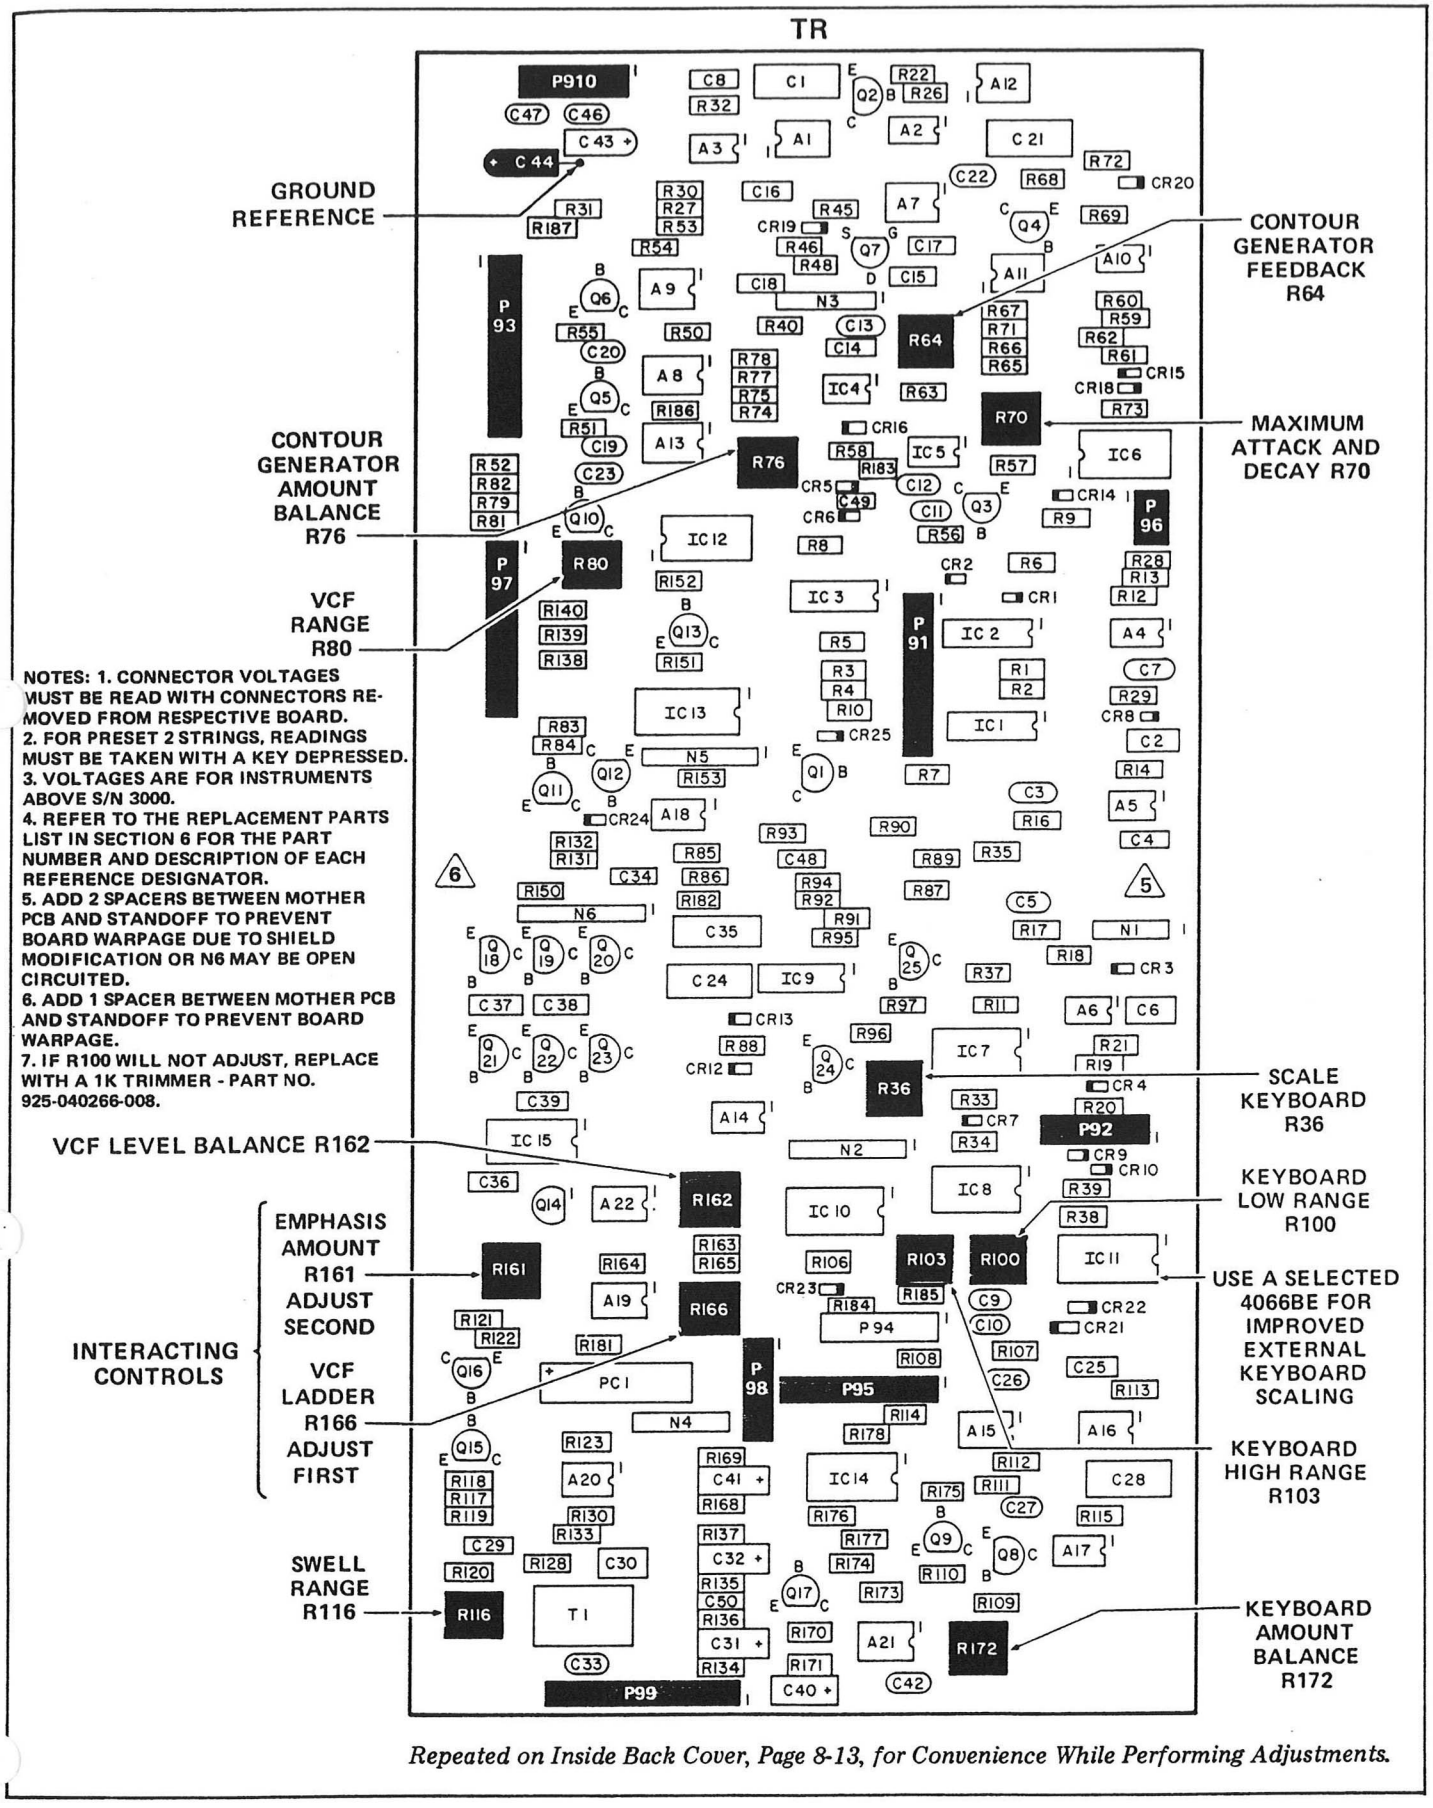
3. Adjust R166 so that the voltage indications anywhere between EMPHASIS full up and EMPHASIS full down are identical within 10 mV DC. Recheck VCF RANGE (step g).

i. EMPHASIS ADJUSTMENT (with dB meter)

1. Depress preset No. 8 and VCF VAR. Position all VCF sliders full down except position EMPHASIS full up. Monitor MIX output, raise VCF GAIN slider.

2. Adjust trim pot R161 until filter regenerates and adjust frequency of regeneration with front panel CUTOFF slider for 440Hz.

3. Raise DIRECT GAIN slider, depress A_4 (440Hz) and zero beat the sawtooth oscillator with the regeneration filter using the front panel fine tune. Return the DIRECT GAIN slider to 0.



Repeated on Inside Back Cover, Page 8-13, for Convenience While Performing Adjustments.

FIGURE 6-2 VOLTAGE CONTROLLED FILTER AND KEYBOARD CIRCUIT PRINTED CIRCUIT BOARD ASSEMBLY

4. Position filter EMPHASIS slider full down and note output level while holding A4 (A440) approximately -25 to -30dB).

5. Position filter EMPHASIS slider full up and adjust trimpot R161 for a 17dB increase over the level noted in step 4. Check each preset for no regeneration.

j. EMPHASIS AMOUNT ADJUSTMENT (without dB meter)

1. Perform VCF ladder balance and VCF level adjustment as directed in steps h and k.

2. Place EMPH slide control full up and all others full down. Monitor output with VCF GAIN, slider up and observe filter oscillation. Adjust trim pot R161 until the oscillator just barely dies out and disconnect oscilloscope.

k. VCF LEVEL BALANCE ADJUSTMENT

1. Perform VCF ladder balancing adjustment as directed in step h. Check that CUTOFF slider is at 5 and all other VCF sliders are at 0.

2. Connect a DVM to pin 1 of A20 and adjust R162 for +4.85V ± 10mV. Check alignment by moving CUTOFF slider fully down and then up. Note that DC output voltage does not vary more than 100mV from lowest to highest value. Recheck ladder balance (step h) and disconnect the oscilloscope and DVM.

l. SWELL RANGE ADJUSTMENT

1. Depress preset No. 8, place all OCTAVE BALANCE and DIRECT GAIN sliders full up.

2. Depress and hold A_4 and adjust R116 for maximum output.

3. Back off from that setting so that the output level drops 1dB (10 percent drop in amplitude).

6.4 REMOVAL

a. If it is necessary to remove a component, remove four screws at the center and left side of the board.

b. Raise board to gain bottom access noting it is hinged at the right side.

6.5 TROUBLESHOOTING

Troubleshoot the TR board using Table 6-1, the circuit description (paragraph 6-1), part location and schematic diagrams (Refer to Volume II). Note that voltage levels and waveforms displayed on the schematic diagram are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part.

TABLE 6-1
POLYMOOG VOLTAGE CONTROLLED FILTER TR BOARD 9 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
KEYBOARD LOWER-UPPER switching does not operate properly	IC1, IC2, IC12
VCF ON-OFF does not operate properly	IC1, IC2, IC12, CR25
ALL-SPLIT mode inoperative	IC1, IC9, CR7, IC7
External foot sustain malfunction	IC3, IC2, CR20, Q1
FINAL DECAY LOCK-MAN malfunction	IC3, Q1
Trigger low works, trigger high inoperative	IC8

TABLE 6-1

POLYMOOG VOLTAGE CONTROLLED FILTER TR BOARD 9 TROUBLESHOOTING (Continued)

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Trigger high works, trigger low inoperative	IC7
Trigger high and trigger low inoperative	IC7, A5, N1
DC trigger present but no AC trigger	A4, N1
String contour generator inoperative	A6, CR4
Modulation oscillator inoperative, no MODULATION S&H or AMT control	A2, Q2, A1*, A3B
MODULATION AMT but no S&H	A8*, Q5, Q7, A7*, C14, IC4, N3
No MODULATION AMT; have S&H	A9*, Q6
Contour generator operating properly but no CONTOUR AMT to VCF	A13*, Q10, trim pot R76 not adjusted properly
Contour generator dead but have trigger	IC5, IC6, A11*, A12, Q3, trim pot R64 not adjusted properly
Contour generator SUSTAIN level malfunction	A10, IC6, Q4, trim pot R70 not adjusted properly
Contour generator operating properly but no ATTACK or DECAY control	IC6, A10, Q4, trim pot R70 not adjusted properly
Single/multiple trigger malfunction	IC9, Q25, Q24
LOWER-UPPER keyboard scaling unequal	Adjust scale keyboard trim pot R36
Keyboard resistor string voltages incorrect	A14, IC10, CR23, N2, trim pots R100 and R103 not adjusted properly
Resistor string voltages correct, keyboard voltage does not change	IC11, A15, A16*, A17A, Q8
Keyboard voltage drifts	IC11, A15

*Replacement requires alignment.

TABLE 6-1

POLYMOOG VOLTAGE CONTROLLED FILTER TR BOARD 9 TROUBLESHOOTING (Continued)

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Glide control does not operate properly	Q9, A16*
No filter CUTOFF frequency control	Q11, Q12, trim pot R80 not adjusted properly, N6
VCF audio path dead	IC12, A18, IC13, Q18, Q23, IC15, A14, A22*, A19*, A20A, N5, C41, trim pots, R161, R162 and R166 not adjusted properly
VCF ladder imbalance	Q18 thru Q23, Q14, A22*, A19*, IC15, trim pots R162 and R166 not adjusted properly
Variable frequency modulation AMT control sliders on front panel do not operate properly	A18B
SWELL control input malfunctions	Q15, Q16, trim pot R116 not adjusted properly, PC1, N4
DIRECT, VCF, MODE and AUX outputs operate properly but BAL MIX output dead	A20B, T1, PO2/SO2
CUTOFF frequency keyboard amount malfunction	A21*, Q17, IC14, trim pot R172 not adjusted properly *Replacement requires alignment.

6.6 POLYMOOG KEYBOARD PROGRAM CONTROL CIRCUIT DESCRIPTION (BOARD 9)

The Program Control board consists of the following major functional blocks:

a. Provides all preset control currents and logic levels to board 7. (Reference and Modulation Oscillator Waveshape and Keyboard Control.)

b. Single and multiple trigger circuits.

c. Keyboard circuit.

d. Contour generator.

IC1 and IC2 are bilateral 8 line to 1 line multiplexers which decode the binary information, from the MASTER VOICE SELECTOR (board 12), applied to their A, B and C inputs. Also from board 12 are the D and $\overline{D}$ lines which are inverted and level translated by IC3 A and B and applied to the INH inputs of IC1 and IC2. These lines alternately switch high and low to determine whether IC1 or IC2 is "on". For presets 1 through 7, IC1 will be active (its INH input low) and for presets 8 through 14, IC2 will be active (its INH input low).

> **NOTE**
> For complete binary coded information associated with each preset, see the TRUTH TABLE 7-8 in the MASTER VOICE SELECTOR (board 12) circuit description.

When a preset is selected it causes one of 50K ohm resistors, R6 through R19, to be connected to the resistor divider comprised of R4 and R5. This connection results in a precise potential of 10.0 VDC at the top of the 50K ohm resistor. This voltage is buffered by one of the amplifiers A1A through A7B, driving P-lines P1 through P14, which drive the preset resistor networks. N3 through N54 will be active and the value of the active resistor determines the magnitude of the current. We now have a means of supplying a specific current for each preset to the instrument program control inputs.

6.7 MODULATION RATE PROGRAMMING

Networks N3 through N8 provide the preset rate control of the pulse width modulation, frequency modulation 1, and frequency modulation 2. The output control current from these networks is fed through bilateral switch IC6, sections A, B and C to connector P94 and finally to the modulation control inputs of board 7.

The MODULATION VAR PRE latch on the LEFT HAND CONTROL board supplies a logic control to P99-1 which will be high (logical 1) for its VAR state and low (logical 0) for its PRE state. This logic signal is applied to gate IC10A (which inverts and level translates) whose output drives the control inputs of IC6 A, B and C through R26 and R27. For all presets when the MODULATION latch is in the PRE state, IC6 A, B and C will be on. Therefore, preset modulation networks N3 through N8 are active. For all presets except 2, 3 and 7, when the MODULATION latch is in the VAR state, IC6 A, B and C will be off. Therefore, preset modulation networks N3 through N8 will be inactive. In presets 2 and 3, CR2 and CR3 will be pulled up to +10VDC by P2 and P3. Therefore, IC6 A, B and C will be forced to the on condition regardless of the state of the MODULATION latch and N3 through N8 will remain active. IC6A preset 7 CR1 will be pulled up to +10VDC by P7. Therefore, IC6A only will be forced to the on condition regardless of the state of the MODULATION latch and N3 and N4 will remain active. IC6 B and C will still be switched off when the MODULATION latch is in the VAR state and N5 through N8 will be inactive. Resistors R26 and R27 provide isolation for the IC10A output through CR1, CR2 and CR3.

IC4 and IC5 switching is accomplished in the same manner as described for IC1 and IC2 except their INH lines are also gated with the previously described logic level from the MODULATION latch. Therefore, with the MODULATION latch in the PRE state, both IC4 and IC5 will be off. In the VAR state, either IC4 or IC5 will be on depending on the preset selected (presets 1 through 7, IC4, and presets 8 through 14, IC5 will be on). Assuming that the MODULATION latch is in the VAR state, one of the output pins of IC4 or IC5 will be connected to the front panel MOD RATE potentiometer R106 through R23. Resistor R22 determines the minimum current and R23 determines the maximum current to be supplied to a control input. There is now a method, as determined by the ouput connection arrangement of IC4 and IC5, to select which one of the three modulators will be controllable by R106 in the VAR state of the MODULATION latch.

6.8 MODULATION AMOUNT PROGRAMMING

Networks N9 through N16 provide the preset amount control of the pulse width modulation low, pulse width modulation high, frequency modulation 1, and frequency modulation 2. The output control current from these networks is fed through bilateral switch IC9, sections A through D, to connector P94 and finally to the modulation control inputs of board 7.

The IC9 switching, as controlled by the MODULATION latch on the LEFT HAND CONTROL board, is the same as the switching described in the MODULATION RATE programming paragraph of this section for IC6 A, B and C except that the only preset that overrides the off state for one of the IC9 sections (MODULATION latch in the VAR state) is preset 7. With preset 7 selected, CR4 will be pulled up to +10VDC by P7 which will force IC9 B and D to the ON state regardless of the state of the MODULATION latch and N13 through N16 will remain active. Sections A and C of IC9 will still be switched by the action of the MODULATION latch.

The switching of IC7 and IC8 is exactly the same as the switching of IC4 and IC5 as described in the MODULATION RATE programming paragraphs of this section. With the MODULATION latch in the VAR state, it will connect one output of either IC7 or IC8 to the wiper of the front panel MOD AMT potentiometer R108. The top of potentiometer R108 is driven by amplifier A8A whose output is nominally at +10VDC. Rear panel MOD AMT jack J1 has been provided so a foot pedal may be used to attenuate the output potential of A8A, thereby having foot control of the modulation amount. Resistors R32 through R54 determine the maximum modulation amount control current. Their connection arrangement determines which modulation amounts will be controlled by the front panel MOD AMT potentiometer R108 in the VAR state of the MODULATION latch.

The Modulation Table 6-3 that follows will help to summarize the programming of modulation rates and amounts in variable and preset.

TABLE 6-3 MODULATION

PRESET	MOD LATCH	MODULATION RATE			MODULATION AMOUNT			FM2
		PWM	FM1	FM2	PWM LOW	PWM HIGH	FM1	
1-14	P	PR	PR	PR	PR	PR	PR	PR

LEGEND

P — PRE state of latch.

V — VAR state of latch.

N — No variable or preset control current.

PR — Internal programming remains active and potentiometers have no control.

VAR — Modulation controlled by RATE or AMT potentiometer.

PWM — Pulse width modulation.

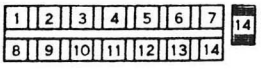
FM1 — Frequency modulation 1.

FM2 — Frequency modulation 2.

NOTE

1. *Modulation control current is the sum of the preset current and the current supplied by the MOD AMT potentiometer.

2. In cases where modulation rates have no control current (N), the modulation oscillator on board 7 will still run at its minimum rate.



6.9 LOUDNESS ATTACK PROGRAMMING

Networks N53 and N54 provide preset control of the loudness attack. The output control current from these networks is fed through bilateral switch IC11A to connector P910 and finally to the loudness attack control input of board 7.

The ATTACK VAR PRE latch on the LEFT HAND CONTROL board supplies a logic control to P94-4 which will be high (logical 1) for its PRE state and low (logical 0) for its VAR state. This logic signal is applied to the control of IC11A. Therefore, IC11A will be off, making N53 and N54 inactive for its VAR state. This ATTACK latch logic level is also applied to IC11C which is used as an inverter and drives IC11B. Thus the IC11B on/off function will be the opposite of IC11A.

The variable state of the loudness attack function has a programmed maximum control current. The variable attack networks N51 and N52 determine this maximum current and are similar to the preset networks but, rather than driving a control input directly, drive A11 A and B. This proportionately changes the output current from N51 and N52 to a voltage to drive the top of the ATTACK potentiometer R109B. The wiper of R109B is tied through R92 to the input of IC11B which, in its on state (VAR state of the ATTACK latch), supplies control current to the loudness control input of board 7.

6.10 FOOT SUSTAIN PROGRAMMING

FOOT SUSTAIN is programmed on for presets 1, 2, 9, 10, 11 and 12 by networks N49 and N50. The resistor in those locations forces current to flow through the base emitter junction of Q5, causing Q5 to pull up the emitter of Q6, forward biasing it and pulling the FTSUB lines of each of the MOTHER BOARD to ground, which turns on the FOOT SUSTAIN. Remaining presets have no resistors programmed, therefore the FTSUB lines stay at -5.5VDC and the FOOT SUSTAIN is off. Rear panel FOOT SUSTAIN jack J2 has been provided to allow the usage of a foot switch to turn the FOOT SUSTAIN on where it is not programmed on.

6.11 MISCELLANEOUS PROGRAMMING

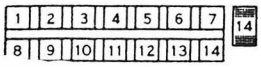
Networks N27 through N48 have no switching associated with them and drive their respective control inputs of board 7.

Networks N19 through N26 are used to drive logic signals to program various switching functions. Whenever a resistor is preset in a network, selecting the associated preset will turn on the output transistor Q1 through Q4, causing its collector to go to ground (logical 0). If no resistor is programmed, the collector will be high (logical 1). Networks N21 through N26 have an extra inversion provided by IC10B, C and D. Assuming a resistor is programmed for a selected preset, the state of the following switching function will be: LOCK/FREE; FREE; FOOTAGE - 16'; FOOTAGE - 4'; ON/OFF, OFF.

The BRIGHTNESS NETWORKS N17 and N18, rather than having a current output, is converted to a voltage drive by summing amplifier A9B. Resistor R55 provides a required offset at the A9B output.

6.12 TRIGGER CIRCUIT

Whenever a key is depressed, a current of approximately 4 microamps is applied to the TRGB line (trigger buss line) from the keyboard. This current is routed to the input of trigger summing amplifier A10A which generates a negative step of approximately 200 millivolts for each key depressed. R65 and C7 filter out unwanted 20kHz which is present on the keyboard and picked up by the TRGB line. C6 rolls off the gain of A10A at high frequencies. The output of A10A drives comparator A10B, whose threshold is approximately 200 millivolts below the zero trigger signal (no keys depressed) output of reference A10A. Depression of one or more keys causes the output of A10B to swing from -15 to about +3.5VDC. This A10B single trigger output is applied to the base of Q7 by R66. The output of trigger summing amplifier A10A is also coupled via C8 to multiple trigger generator A9A. The positive input of A9A is biased to the -5.5VDC rail via R72. The negative input reference is approximately 200 millivolts more negative, derived from resistors R68 and R71. Each time a key is depressed, a step on A10A causes a 5 millisecond negative going pulse on A9A. A small amount of regeneration providing Schmitt trigger action is accomplished by R73 and C9. The multiple trigger output of A9A drives the base of Q7, which is the S-TRIGGER output and will be at +15VDC (trigger off). When a key is depressed, the A10B single trigger output goes high, turning Q7 on and pulling its collector to ground



(trigger on). If a second key is depressed, while holding the first, multiple trigger amplifier A9A fires negative for 5 milliseconds, and sinks all the current that was supplied to Q7 by A10B. The collector of Q7 will return positive during this time, which is a momentary loss of trigger, and then returns to ground which is a new or multiple trigger. Subsequent keys depressed will cause this action to repeat. When all keys have been released, the Q7 collector returns positive and the trigger is off. Rear panel switch SW1 and jack J3 (for foot switch control) provide switching between the single and multiple trigger modes. With SW1 in the open position, the circuit functions as described above and multiple triggering is the result. Sliding SW1 to the closed position shunts the multiple trigger output of A9A to ground, causing single triggering.

> **NOTE**
> In order for a trigger foot switch installed in J3 to function, SW1 must be in the MULTIPLE position.

6.13 KEYBOARD CIRCUIT

The keyboard circuit consists of the following functional blocks:

1) Current source.

2) Sample and hold.

3) Glide circuit.

The keyboard assembly has a monophonic section which is a resistor string consisting of seventy-one 100 ohm resistors in series and a normally open switch contact between the junction of each resistor in the string and a common buss bar. When a key is depressed, a contact connects a point on the resistor string to the buss.

A12B, in conjunction with R81, R83 and the keyboard resistor string form a differential amplifier with the differential inputs are tied together at R110. Since the keyboard resistor string is in the feedback loop, it will be driven by a constant current. Rear panel KEYBOARD SCALE potentiometer R110 adjusts this constant current from a nominal 833 microamps, ± 10 percent. Since R110 moves both differential inputs together (the differential input will always be zero), R81 is equal to R82 and the total resistance of the keyboard resistor string is equal to R83 (seventy-one 100 ohm resistors in series and is very close to the value of R83), provided no keys or only one key is depressed, the output of A12B will always be 0.0VDC regardless of the setting of R110. If more than one key is depressed, the resistors in the string between the depressed keys will be shorted out, reducing the resistor string total resistance. The voltage at the top of the resistor string now remains constant. However, the output of A12B will increase to maintain the set current.

Assuming the SCALE potentiometer was set to drive the nominal current of 833 microamps through the resistor string, the voltage delivered to the buss by the switch contacts, due to the IR drops of the 100 ohm resistors, would rise from 0.0VDC (lowest note) at a rate of 83.3 millivolts per semitone, or 1 volt per octave. Since the SCALE potentiometer can change this current ± 10 percent, this voltage rise would also change ± 10 percent.

The keyboard buss voltage is applied to holding capacitor C10 and buffer A12A through bilateral switch IC11D and R88. When a key is depressed, multiple trigger amplifier A9 (described in the Trigger Circuit paragraph in this section) fires a 5 millisecond negative going pulse which is inverted by Q8 and turns IC11D on. Holding capacitor C10 charges through R88, which limits current slugs, to the buss voltage and A12A buffers it to avoid loading of C10. The keyboard buss voltage is now stored at the A12A output. Since this holding circuit is triggered by a multiple trigger, every time an additional note is depressed, a new sample will result. However, because the keyboard circuit has high note priority, only successively higher notes depressed will cause a change in keyboard control voltage at the A12A output. R85 and R86 offset the output of A12A by -83 millivolts or down one semitone. This makes the lowest F on the keyboard 0.0VDC which is compatible to other MOOG products. R87 is in series with the A12A output to prevent oscillations that might result when driving fairly high cable capacitances. Rear panel KEYBOARD RANGE potentiometer R111 through R84 allows an adjustment of ± 1 semitone to compensate for internal and slave

unit offsets. The A23A output drives the VCF on board 8 directly and one end of the rear panel GLIDE potentiometer R112.

The glide time will be exponential as determined by the time constant formed by the GLIDE potentiometer R112 and capacitor C12. Buffer A13 drives the KBD, C.V. OUT jack J4 through R90 which isolates the A13 output from cable capacitance which could cause oscillations. C11 rolls off the high frequency gain of A13 to further reduce the possibility of oscillation. Note that the glide circuit is after the sample and hold circuit therefore the keyboard control voltage will continue to glide up or down until it reaches the last control voltage sampled, after all keys have been released. GLIDE ON/OFF jack J5 has also been provided to allow foot switch control of glide.

6.14 FILTER CONTOUR GENERATOR

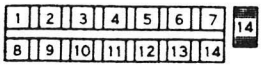
The filter contour generator for Polymoog Keyboard is used to generate a contour which modifies the cutoff frequency of the voltage control and filter for preset voices 9 and 10, the brass voices.

The filter contour generator is triggered by the S-trigger appearing at the collective of Q7. Either single or multiple triggering of this contour generator is controlled by the operating mode of the S-trigger signal itself. The S-trigger signal is differentiated by C13 and R94 and coupled to the gate of the buffer FET Q13 via R95. R95 is sufficiently large to prevent damage to A13 on positive transistions of the S-trigger signal. The contour signal itself appears at the positive side of the integrating capacitor C14. Assume for circuit description purposes that this contour signal is initially at 0VDC. The negative going transition applied to the gate of Q13 causes the potential on pins 3, 13 and 10 of IC12 to go to +15VDC. This in turn causes Q11 to be turned on which pulls down the voltage on pins 5 and 6 of IC12. This causes Q10 to be turned on, latching the potential on pins 3, 13 and 10 of IC12 to +15V. Thus, Q10 and Q11 form a complimentary type latch. The S-trigger signal appearing on the collector of Q7 is directly coupled to the gates of Q14 and Q16 in IC13 and as long as a note is held depressed, transistor Q16 is turned off and transistor Q14 is turned on. In general, this contour generator works by switching in various sources of current during the attack, sustain and decay phases.

Attack current is provided through one of the latch transistors in IC12, namely Q11. As previously noted, during initial depression of a key, Q11 is turned on. After initial triggering, the voltage on pins 3, 13 and 10 and IC12 is +15VDC, which turns on Q12. This pulls the voltage applied to pin 10 of IC13 to 0VDC and holds the decay path transistor Q15 off. During the attack phase, current supplied via pins 5 and 6 of IC12 and Q11 in IC12 causes the potential on the integration capacitor C14 to begin to rise linearly. This voltage continues to rise until transistor Q11 turns off because of back gate bias effects which occur approximately at a potential to 7-1/2V. The attack current applied to pins 5 and 6 of IC12 is derived either from the preset values determined in resistor networks N53 and N54 or from the variable attack control circuit to be described later.

When the attack source transistor Q11 cuts off, the potential on the gate of Q10 goes to +15V which turns off Q10, causing the voltage on pins 3, 13 and 10 of IC12 to return to 0VDC. This turns the inverting transistor Q12 off and causes the potential applied to pin 10 of IC18 to go to +15VDC which turns on the decay path transistor Q15. If a note is still depressed, then, as mentioned previously, the sustain level transistor Q14 is turned on. This applies a potential, determined by the resistor divider network consisting of R102 and R103, to be applied to the decay resistor R104 through Q14 and Q15. This is the decay toward sustain level with a note held depressed. Note that the voltage on the integration capacitor C14 will then approach the sustain level with a time constant determined by the resistor R104 and the integration capacitor C14. When all notes are released, the S-trigger signal on the collector of Q7 returns to +15VDC which turns off the sustain level transistor Q14 and turns on the final decay level transistor A16 in IC13. Now the voltage on the integration capacitor C14 starts toward 0VDC with a time constant determined by R104 and C14. This final decay path is accomplished through Q15 and Q16.

It is interesting to note that transistors Q10 and Q11 in IC12 serve as a combined latch/comparator. This latch is turned on when a note is depressed and stays on until the voltage across the integration capacitor C14 has reached its maximum level, turning off transistor Q11. In summary, the attack current is supplied via Q11, the decay toward sustain level current is supplied via Q14 and Q15, and the decay toward the final sustain level (namely 0VDC) is accomplished through Q15 and Q16.



The attack mode current applied to pins 5 and 6 of IC12 is derived either from the preprogrammed attack supplied through R96 and the analog gate, IC6D, or from the collector of Q9 and diode CR5. If the attack control mode is preset, then the current is supplied via IC6D because the control line applied to pin 6 of IC6D is at +15VDC, turning on the gate and turning off the current source transistor Q9. When the attack control mode is in variable, the potential applied to pin 6 on IC6D is at 0VDC. This turns off the gate and applies a drive voltage to the base of Q9 which allows current to flow via the front pan attack potentiometer R109A through R99 (th minimum attack time resistor), Q9 and CR5 to pir 5 and 6 of IC12.

6.15 TROUBLESHOOTING

Troubleshoot the program control TR9 boar circuit using Table 6-4, the circuit description (para graph 6.6) and part location and schematic diagram in Volume II.

TABLE 6-4
POLYMOOG KEYBOARD PROGRAM CONTROL TR BOARD 9 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Preset pulse width modulation rate defective	IC6B, N3, N4
Preset pulse width modulation amount high	IC9A, N9, N10
Preset pulse width modulation amount low	IC9C, N11, N12
Preset frequency modulation 2 rate defective	IC6A, N5, N6
Preset frequency modulation 2 amount defective	IC9D, N13, N14
Preset frequency modulation 1 rate defective	IC6C, N7, N8
Preset frequency modulation 1 amount defective	IC9B, N15, N16
VAR (Modulation controlled by RATE potentiometer) pulse width modulation RATE defective	IC5, R106 (Front Panel)
VAR (modulation controlled by RATE potentiometer) frequency modulation 1 or 2 RATE defective	IC5, IC4, R106 (Front Panel)
Brightness of notes on entire keyboard defective	A9B, N17, N18

7.1 LEFT HAND CONTROL PANEL CIRCUIT DESCRIPTION (BOARD 10) - POLYMOOG

Circuitry contained on the left hand control panel (CL) provides direct digital control signals and control currents for various variable functions in a manner similar to that described for the right hand control assembly. (Refer to Paragraph 7.6.)

Gates G1 thru G3 comprise a tri-flop set to one of three stable states by switches SW1 thru SW3. These switches control selection of SAWTOOTH only, RECTANGULAR waveshape only or sawtooth plus rectangular waveshape for the lower two octave keyboard section. In addition to control of this latch by switches SW1 thru SW3, a particular state may be selected for each of eight presets via programming diodes CR1 thru CR8, CR9 thru CR16 and CR17 thru CR24. These diodes are driven by the S1 thru S8 lines connected to the front panel preset control pushbuttons on the mode selector panel. When a particular preset is selected, the respective S line goes to 0 VDC setting a particular status of this latch comprised of G1 thru G3. Programming is accomplished by putting a diode in one of three possible positions with only one diode attached to the S1 line, S2 line, etc. Thus a total of eight diodes is required to program the status of this tri-flop for all eight presets. A particular state of this tri-flop is active when the respective G1 thru G3 output is low (0 VDC). The sawtooth only and rectangular only latched sections drive open collector gates G7 and G8. These gates are used to inhibit the nonselected waveform via a shutdown diode on the TL board. For example, if switch SW1 is depressed, the output of G1 goes low and the output of G7 goes high. This G7 high signal is applied to the rectangular pulse width control section driving the mother board buss line negative which deletes any rectangular output waveform on the mother board.

A second tri-flop, comprised of G4 thru G6 with associated drivers G9 and G10, operates in a manner identical to that described for the LOWER KEYBOARD and is used to control waveshape selection for the UPPER KEYBOARD.

Octave pitch selection for the sawtooth and rectangular ranks is controlled by two latches comprised of G11/G12 and G13/G14. The first latch determines whether FOOTAGE for the sawtooth rank is 8 or 4 and the second latch determines whether FOOTAGE for the rectangular rank is 16 or 8. Programming of these two latches for various preset modes is determined via diodes CR49 thru CR56, CR57 thru CR64, CR65 thru CR72 and CR73 thru CR80 in a manner identical to that described previously.

VAR-PRE tuning of the sawtooth rank is controlled by a latch comprised of G15, G16 and the associated CMOS switch package and inverter IC8. The latch may be controlled either by front panel VAR-PRE switches SW11 or SW12 or via the RP1 and VP1 lines which go negative when any one of eight presets is selected or VARIABLE mode No. 9 pushbutton is depressed, respectively. This latch connects either preset network N1 or ∿ RANK TUNE control R20 to the POITN line via the FET switches contained in IC8. The various FETs in IC8 are connected to comprise a level translator and inverter and two N channel FETs for alternate switching action. The ∿ RANK TUNE control R20 feeds current to the POITN line when the appropriate FET is on via feed resistor R17. Bias resistor R18 sinks current so that when the ∿ RANK TUNE control is centered, approximately no current flows to the POITN line. Diode CR81 is used to prevent input voltage on pin 5 from going negative when the FET switch associated with pin 5 is off, preventing any off current from leaking to the POITN line via the substrate of IC8.

The latch comprised of G17 and G18 controls VAR-PRE selection of FREQUENCY MODULATION rates and amounts for the two oscillator ranks via FET switch packages IC9, IC10, IC12 and IC13. The TTL level from the latch is level translated and inverted in IC9. The inverted signal is fed in common to the remaining three switch packages. This inverted signal from pin 10 of IC9 is used to drive these switch packages in a manner similar to that described for the CR board whereby each pack acts as a single-pole,

double-throw switch connecting either the associating resistor network or the related front panel control to the output port.

Programming resistor packs N2, N3, N5 and N6 are driven in common by preset lines P1 thru P8 of which one, at any given time, is 10.0 VDC while all others are zero. Pin 2 of these four resistor programming packs is connected to the emitter of a drive transistor whose collector is connected to string mode preset line P1. The bases of transistors Q1 thru Q4 are tied together in common and are driven by string contour generator line MACG via limit resistor R21. This common connection is labeled XX. By placing the resistor in position 2 of the resistor pack, the drive voltage applied to pin 2 of these packs is modulated by the string contour generator contained on the TR board to provide delayed frequency modulation amounts and rates when the instrument is in the STRING mode.

The latch comprised of G21 and G22 controls the VAR-PRE selection for low and high sawtooth level via switching packs IC11 and IC14 operating identically to those previously described. The latch may be controlled either by VAR-PRE switches SW15 and SW16 on the front panel or the RP1 and VP1 lines for automatic status setting of this latch.

Switching the instrument between the LOCK and FREE modes is accomplished by a latch comprised of G25 and G26. This latch may be programmed to a particular state for each of the presets via programmed diodes CR82 thru CR89 and CR90 thru CR97.

Variable or preset control of the RECTANGULAR WAVESHAPE PULSE WIDTH, PULSE WIDTH MODULATION and MODULATION RATE is controlled via a latch comprised of G23 and G24 and switch packs IC15 thru IC20. The status of this latch is controlled by front panel VAR-PRE switches SW17 SW18 or via the RP1 and VP1 lines as described previously. The switch packs in this section provide for VAR-PRE control of the rectangular pulse width for the lower keyboard section, the pulse width modulation for the lower keyboard, the rectangular waveshape for the upper keyboard and the pulse width modulation for the upper keyboard. Note that the program networks for the pulse width modulation low and high circuit have pin 2 connected to the emitter of a transistor which is driven from the XX line. This XX line is connected to the string contour generator providing delayed pulse width modulation when the instrument is in the string mode.

Circuitry associated with the pitch controller-RIBBON is contained on the CL board and is comprised of R59 thru R61. The pitch controller is comprised of a 10K resistor over which is stretched a metallic contact element. The element does not normally touch the distributed 10K resistor element R62. When the ribbon is depressed, this contact element, connected to the RIBR line, touches some point on the distributed resistor element causing a position dependent voltage between approximately -0.5 and +0.5 VDC to appear on the RIBR line. Pitch controller center adjust trim pot R60 provides for center trimming of the ribbon element, that is, an adjustment of the end point voltages of the ribbon so that when the ribbon element is depressed exactly in the center, 0.0 VDC appears on the RIBR line.

Filter glide control is accomplished via divider front panel EXT KB GLIDE control R63 and feed resistor R64 and applied directly to the CR board. This particular instrument function is not programmed for the various presets since it is used primarily for external synthesizer effects.

The elements labeled CP1, CP2 and CP3 are circuit protection Zener diodes providing overvoltage protection for the +5, +15 and -15 supply voltages, respectively. These power Zener diodes clamp voltages at approximately +6.8, +16 and -16 volts respectively should a power supply overvoltage occur.

The preset switch lines SP1 thru SP9, RP1 line and preset drive lines P1 thru P8 are connected to the CR board via connectors P104 and P105.

Power enters and leaves the CL board through connectors P102 and P107 and distribution rails on this board serve as the master ground and supply reference points for the +5, +15 and -15 VDC supplies. Both the supply and ground sense lines for these two supplies are referenced to the left hand control board at connectors P102 and P107.

NOTE

The power supply output voltages must be checked and adjusted if necessary (refer to Table 8-1) prior to all troubleshooting and alignment procedures.

7.2 LEFT HAND CONTROL PANEL ASSEMBLY ALIGNMENT

a. PITCH CONTROLLER CENTERING ADJUSTMENT

1. Connect dc voltmeter between pin 1 of P73 (terminal 24 of board 10) and ground. Depress PITCH CONTROLLER at the center directly above the raised rib on the ribbon and adjust trim pot R60 for a voltage indication of 0.0 ± 0.1 VDC. (Volume II).

7.3 TROUBLESHOOTING

Troubleshoot the left hand control printed circuit board using Table 7-1, the circuit description paragraph 7.1, and part location and schematic diagrams in Volume II.

7.4 POLYMOOG KEYBOARD LEFT HAND CONTROL BOARD CIRCUIT DESCRIPTION (BOARD 10)

The LEFT HAND CONTROL (CL) board in Polymoog Keyboard provides the following major functions:

a. Power supply distribution.
b. All VAR/PRE, ON/OFF logic switching.
c. -5.5 VDC power supply.

VARIABLE/PRESET control for the ATTACK is accomplished through gates IC1C and IC1D which constitute a cross-coupled latch, driving panel indicators L1 and L2. IC1D pin 13 will be low (0 VDC) in the PRE state and high (+5 VDC) in the VAR state. This output is routed through open collector output inverter IC2C to board 9.

VARIABLE/PRESET control for the MODULATION is accomplished in the same manner with gates IC1A and IC1B driving panel indicators L5 and L6. IC1B pin 4 will be low in the PRE state and high in the VAR state and is routed to board 9.

ON/OFF control for BASS FILTER is also accomplished in the same manner with gates IC2A and IC2B driving panel indicators L3 and L4. IC2A pin 3 will be low for the ON state and high for the OFF state and is routed to inverter IC2D.

The RPI line from the MASTER VOICE SELECTOR board 12 is applied to P106 pin 1 and to one input of each of the three latches described above. Whenever one of the fourteen preset buttons is depressed, the RPI line goes low. This will force the ATTACK and MODULATION latches to their PRESET state and the BASS FILTER latch to its OFF state.

Audio output from the LOW MOTHER board is applied to P101 pin 1 and drives the top of front panel BAL 1 through 2, potentiometer R19 and the BASS FILTER (on board 8) by way of AC coupling capacitor C3. Assuming the BASS FILTER latch is in the OFF state and there is no plug inserted in the rear panel BASS OUT jack J10, IC2D pin 11 will be low (described above). Therefore, IC3A will be off, opening the low audio path to the BASS FILTER, and since IC3B is used as an inverter, its output will be high. This will turn IC3D on and complete the low audio path to the filter drive amplifier on board 8. If the BASS FILTER is turned ON, the states will be reversed and IC3B will be on, completing the audio path to the input of the BASS FILTER. IC3D will be off, breaking the audio path to the filter drive amplifier. The output of the BASS FILTER is routed through front panel BASS LEVEL potentiometer R55 to the BASS OUT jack J10, via C1, and to bilateral switch IC3C. The control input of IC3C is connected to the ring terminal of J10. With no plug inserted in J10 it will be high, turning IC3C on and completing the audio path to the mix output amplifier on board 8. Inserting a mono (one circuit) plug in J10 will short the ring to ground, turning IC3C off and severing the audio path to the mix output amplifier.

The -5.5 VDC supply rail is developed by inverting amplifier A1. Vcc is used as the reference voltage and applied through summing resistor R10. Emitter follower Q1 is connected inside the feedback loop to provide current gain. R12 reduces the possibility of oscillation and R13 lowers the power dissipation in Q1.

7.5 TROUBLESHOOTING

Troubleshoot the left hand control board in accordance with Table 7-3, the circuit description paragraph 7.4 and the parts location and schematic diagrams contained in Volume II.

TABLE 7-3

7.6 RIGHT HAND CONTROL AND MASTER PRESET ASSEMBLY CIRCUIT DESCRIPTION (BOARD 11) - POLYMOOG

The right hand control and master preset assembly (CR) performs three major functions: (1) provides control current and logic levels to the top boards; (2) contains preset (load) logic and drive circuitry; and (3) provides audio reference voltage V_{ch} = 4.85 VDC) and -5.5 VDC voltage rail. (See Volume II.)

The CR board contains the VAR-PRE switching for the voltage controlled filter and loudness contour sections. Variable preset control for the voltage controlled filter is accomplished via G1 and G2, a cross-coupled latch driving front panel indicators L1 and L2. Switching of this latch is accomplished via VAR and PRE switches SW1 and SW2. A particular state of the latch is active when the associated output line is low "0." For example, the voltage controlled filter is in the VAR mode when pin 13 of IC1 is low. The TTL latch, comprised of G1 and G2, is routed directly to the top right board (board 9) containing the voltage controlled filter for VAR-PRE gain compensation.

In addition, the output of this latch is applied to a level translator comprised of an N channel transistor and R3. When input voltage at pin 6 of IC2 drops to ground potential, the voltage at pins 3 and 8 increases to +15 volts turning off the P channel transistor associated with pin 2 of IC2 and causing the voltage on pins 1 and 10 to go to 0. This output on pin 10 of IC2 is used as a common drive line (ZZ line) to IC3 thru IC10 which perform the VAR-PRE current switching for their associated functions.

When the voltage controlled filters are in the variable mode, the voltage at pin 3 of IC2 is high turning on the N channel transistor associated with pin 4. This allows current to be supplied from the front panel S&H slide control via R6 to the sample and hold control node, PVSHN. At the same time, voltage on pin 10 of IC2 is low, turning off the N channel transistor associated with pin 9 preventing any current from preset resistor network N5, driven by the P lines (P1 thru P8), from reaching the sample and hold control node, PVSHN. Thus IC2 acts as a single-pole, double-throw switch routing current from either the front panel slide control or from resistor network N5 to the control node.

The ZZ drive line controls the remaining functions associated with the voltage controlled filter. This ZZ line is directly coupled via pin 3 to all of the N channel FETs which switch in control currents for the preset modes. In addition, this ZZ line is coupled to pin 6 of each of these switching packs and inverted by the P and N channel FETs associated with pins 14 and 7, respectively (this inverter drives the N channel FET coupled to the front panel slide control current source). Thus IC2 thru IC10 are all simultaneously switched between the VAR-PRE modes via the latch comprised of G1 and G2. The P1 thru P8 lines are driven from buffer amplifiers and only one of eight P lines is active at any one time, determined by which preset mode is selected. The active preset mode is indicated by the seven segment display on the mode selector control assembly.

The VAR-PRE latch comprised of G1 and G2 is also controlled by the RP1 and VP1 lines. Whenever one of the eight preset pushbuttons is depressed, the RP1 line goes negative (0 VDC) forcing pin 10 of IC1 to go to 0 placing the latch in the preset mode. Whenever pushbutton No. 9 on the mode selector panel is depressed, the VP1 line goes negative forcing the latch comprised of G1 and G2 to go to the VAR mode. This latch may thereby be switched either locally via front panel switches or remotely through mode selector controls.

The ON-OFF, LOWER-UPPER and ALL-SPLIT modes of the VCF are controlled by three similar latches comprised of G3/G4, G5/G6 and G9/G10. The ON-OFF latch is forced to the ON state whenever either VP1 or RP1 line goes active "0." Similarly, the ALL-SPLIT latch is forced to the ALL mode. In addition, the ALL mode is coupled to the LOWER-UPPER latch through the top right board such that whenever the VCF is in the ALL mode, the VCF keyboard mode latch is forced into the UPPER state.

The brightness latch is comprised of gates G7 and G8 and is switched via the RP1 and VP1 lines as described previously. This latch drives CMOS analog switches in IC16, a configuration identical to that of IC2. However, the brightness does not have any associated front panel control but rather a fixed current provided via R32 when the brightness control is switched to variable (by VP1).

Front panel switching control for the RESONATOR section is accomplished via gates G11 thru G22. Gates G11 thru G13 are cross-coupled in such a manner to provide a tri-flop. Whenever anyone of these three gates is on, that is, 0 VDC, it forces the output of the two remaining gates high which gives a self-consistent stable state. Switching between the ALL,

UPPER and LOWER modes is accomplished by switches SW9 thru SW11. The outputs of this tri-flop are encoded by gates G19 and G20 so that when the tri-flop is in the ALL mode, both outputs of G19 and G20 are +15 VDC and if the tri-flop is in either the UPPER or LOWER mode, respective gate G19 or G20 is positive while the other is negative. These lower-upper switching signals are routed to the top center board for audio switching control. Gates G14 thru G16 provide resonator and mode ON-OFF control. Gate G15 is currently not used and its output is forced to a "1" by grounding pin 9. Thus gates G14 and G16 act as a simple cross-coupled latch controlled by ON-OFF switches SW12 and SW13 on the front panel. The output of G21 is routed to the top center board for ON-OFF audio switching of both the RESONATOR and MODE audio paths.

The RESONATOR section is forced into the ALL and ON modes whenever one of eight presets is activated via the RP1 line and R97. When push-button No. 9 is depressed, the resonators are forced into the ON mode via the VP1 line but keyboard mode switching is unaffected.

The FINAL DECAY LOCK-MAN mode is controlled by the cross-coupled latch comprised of G17 and G18 which is controlled by front panel switches SW14 and SW15. The RP1 line sets this latch to the MAN mode, defeating unconditional final decay.

The amount of keyboard control voltage fed to the voltage controlled filter is determined by preset network N10 and front panel KB variable control R42. In this particular case, the variable control feed resistor and the CMOS switching pack are contained on the TR board. The loudness contour VAR-PRE switching is accomplished via the cross-coupled latch comprised of G23 and G24 which operates in a manner identical to those described for the voltage controlled filter. The configuration of IC19 is the same as for IC2. In this case the XX line performs the same function as the ZZ line which is the common drive line for the various switching packs within a section.

The CR board also contains logic associated with preset mode switching which controls the front panel seven segment indicator and P lines which drive the preset resistor packs. The SP1 thru SP8 lines are connected to momentary contact switches on the front panel via connector P115. In addition, the VP1 line is connected to No. 9 pushbutton via pin 1 of connector P115. Whenever one of No. 1 thru 9 mode selector pushbuttons is depressed, the respective SP line goes to "0." Encoder IC24 converts the linear input code on the SP lines to binary form on the A1, A2, A3 and GS lines. Whenever any one of the SP1 thru SP8 lines is switched to ground potential, the GS line goes negative in turn causing the output of G32 to go positive causing the RP1 line to go negative via G33 if, and only if, the decimal point line, DECPT is positive (the OFF state for the decimal point). When No. 9 pushbutton is depressed, the output of G25 goes positive. Whenever any one of the SP lines goes negative, or pin 5 on IC24 goes positive, the output on pin 15 which is coupled to Schmitt trigger gate G29 via R64 goes positive. Capacitor C4 provides for approximately 1 msec delay before G29 goes negative. This negative going transition is differentiated producing a narrow pulse via C6 and R66 and is applied to second Schmitt trigger gate G30 to provide a narrow positive pulse to the clock input of quad latch IC28. At the time a clock pulse appears on pins 4 and 13 of the quad latch, a binary representation of the preset number is present on pins 2, 3, 6 and 7. This quad latch remembers (in binary) which preset (mode) pushbutton was pushed last. The outputs of the latch are further encoded via gates G34, G35 and G40 to generate the IDLA-D code applied to the seven segment decoder driver on the mode selector control board. In addition, the binary code from the quad latch is applied to level translator gates G36 thru G38 to provide 0 to 15 VDC drive for mode selection switching on the TC board. These binary encoded versions of the preset number are 15 volt signals identified as SPB lines and drive analog switch A21 contained in IC31.

Decoder IC31 is a bilateral 8 to 1 analog multiplexer. The binary code presented at pins 9 thru 11 of IC31 causes one of the 50K ohm resistors R89 thru R96 to be connected to the resistor divider comprised of R87 and R88. This connection results in a precision potential of 10.0 VDC at the top of the 50K ohm resistor. This voltage is buffered by one of follower amplifiers A2A, A2B, A3A etc., driving the P lines which drive the preset resistor networks for preset control of the various instrument variables.

The VP1 line is connected directly to No. 9 pushbutton switch on the front panel. The RP1 line is derived from AND gate G33 and is enabled via decimal point line DECPT, whose origin is the Q output of the flip-flop in IC26. When the decimal point switch on the front panel is depressed, pin 1 of P112 goes to ground. The RC network comprised of R61 and C2 provides switch debouncing for Schmitt trigger G27 which drives the clock input of the flip-flop. This

clock pulse causes the flip-flop in IC26 to reverse its state, that is, to toggle. Thus successive depressions of the decimal point pushbutton cause the decimal point line to go ON and OFF. If the decimal point light on the front panel is on, the DECPT line is a "0" and RP1 gate G33 is disabled. Thus when the decimal point light is on, depression of one of the eight presets does not reset the VAR-PRE latches on the control board to the PRE mode. Therefore the decimal point pushbutton acts as a cancel defeat.

In the current Polymoog, transistors Q3 and Q4 have been removed. This results in a 0 potential being applied to pins 1 and 3 of IC26 which holds the preset line, pin 10 of IC26, inactive. Thus gate G26 in IC26 is not used.

The +4.85 VDC audio reference rail voltage (V_{ch}) and the -5.5 VDC rail voltage are derived from the +15 VDC source by a voltage divider comprised of R70 thru R72. The divided down voltage is applied to the +4.85 VDC regulator comprised of A1A, R77 and power transistor Q1. The output voltage is fed back to high gain amplifier A1A via R74. The current for the +4.85 VDC supply is drawn from V_{cc} (+5.0 VDC) via the collector and emitter of Q1. This arrangement prevents the output voltage of the +4.85 VDC regulator from going above 5.0 VDC should Q1 short. The +4.85 VDC supply serves as the reference for the -5.5 VDC supply via trim pot R75 and resistor R76. Amplifier A1B and power transistor Q2, along with feedback resistor R79, provide a conventional power regulator which may be trimmed to exactly -5.5 VDC using trim pot R75. The device labeled CP1 (circuit protector No. 1) is a power Zener diode rated at 12 volts. The two supply potentials discussed here are used to power all 71 modulator boards which may be damaged if the voltage across the modulator boards exceed 15 volts. Power Zener diode CP1 not only provides protection against this potential disaster but absorbs very fast voltage transients which might occur due to line voltage surges, static, etc.

Connector P111 applies power from the left control board to the right control board and from this board to other Polymoog circuitry.

7.7 RIGHT HAND CONTROL AND MASTER PRESET ASSEMBLY ALIGNMENT

a. +4.85 VDC ADJUSTMENT

1. Connect d-c voltmeter between emitter of Q1 and ground (green wire on accessory connector) and adjust trim pot R71 for a voltage indication of 4.85 VDC ± 10 mv. (Refer to Volume II.)

b. 5.5 VDC ADJUSTMENT

1. Perform +4.85 VDC adjustment (step a above) and connect voltmeter to emitter of Q2. Adjust trim pot R75 for a voltage indication of -5.50 VDC ± 10 mv. (Refer to Volume II.)

7.8 TROUBLESHOOTING

Troubleshoot the right hand control board by referring to the circuit description, paragraph 7.6, Table 7-5 and the part location and schematic diagrams in Volume II.

TABLE 7-5

POLYMOOG RIGHT HAND CONTROL CR BOARD 11 TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENTS
LOUDNESS CONTOUR VAR-PRE control or keyboard response defective	IC18, L18, L19
KB DYN control R47 response defective	IC19
UPPER KEYBOARD D/R control R49 response defective	IC20, N14

7.9 POLYMOOG MODE SELECTOR CONTROL CIRCUIT DESCRIPTION (BOARD 12)

The mode selector control circuit board (PRE) is mounted behind the front panel extrusion and contains eight preset pushbuttons, a No. 9 pushbutton which is the variable mode, a cancel PART/FULL "." pushbutton, a numeric decorder/divider and a numeric readout. (Refer to Volume II.)

When one of preset switches SW1 thru SW9 or PART/FULL "." switch is depressed, the respective SP control line to the right control board is connected to ground. This causes a binary coded version of the switch number to be stored in a latch circuit and returned to the mode selector control via the IDLA-D lines which drive numeric decoder/divider IC1. This decoder/divider drives numeric readout L1 via resistors R1 thru R8. Approximately 30 milliamperes are supplied to each selected segment in the seven segment numeric readout.

7.10 MODE SELECTOR CONTROL BOARD REMOVAL

a. Remove the right and left control boards from the front panel extrusion.

b. Remove four Phillips head screws at the corners of the mode selector board and unplug connector between the right control board and mode selector board and remove board.

7.11 POLYMOOG KEYBOARD MASTER VOICE SELECTOR (BOARD 12)

The MASTER VOICE SELECTOR board is mounted behind the center front panel and contains a series of preset circuit buttons numbered one through fourteen. Each button is identified on the front panel as to the type of sound produced such as STRING, PIANO and so forth. A circuit description of the board follows supplemented by Table 7-8.

IC1 on board 12 is an 8 line to 3 line encoder which converts its decimal input to binary on its A, B, and C outputs. Depressing any one of the fourteen preset buttons causes IC1 to transfer the binary code to its A, B, and C outputs and forces the EO output to a logical 1 (positive). It is important to note that IC1 does not have the capability to store or retain data; therefore, correct data is only displayed while a preset button is being held.

IC2, C1, C2, R2 and R3 comprise a one-shot that develops a delayed 10 usec negative going (at pin 13) and a positive going (at pin 8) pulse every time the IC1 EO output goes high. The delay before the one-shot pulse and the EO output going high is caused by the EO output not being a direct pull-up for C1. CR3 is back biased by the EO output going high; therefore, C1's only source of charge current comes from IC2's input current. The delay time will be equal to the time it takes C1 to charge enough to exceed the threshold of IC2. Since IC2 has Schmitt inputs it will respond predictably to slow moving input voltages.

IC3 is a quad bistable latch which transfers data from its inputs to its outputs when its clock input is high. When IC3's clock input returns to a logical 0, data that was present on its inputs at the time of the transition is retained on its outputs until another clock pulse is received. The one-shot positive going delayed pulse from the IC2 described above is used to supply the clock pulse to IC3. The delay in the one-shot is required to insure enough set-up time for IC3 (time before clock pulse is received and the data preset on the inputs). If this delay were not employed, IC3 would receive data on its inputs and a clock pulse at virtually the same time which could cause dropped or missing pieces of data.

NOTES

1. L — Ground (OV.)
2. H — Positive (3.5V to 5V)
3. B — Blank
4. Active Low — A low level state will be read as a binary 1 and a high level state will be read as a binary 0.
5. Active High — A low level state will be read as a binary 0 and a high level state will be read as a binary 1.

Summarizing the preceding paragraphs:

a. Preset button depressed.

b. IC1 converts the applied input data to binary on its A, B, and C outputs.

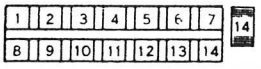
c. IC1 EO output starts the delay which fires the IC2 one-shot.

d. IC2 one-shot transfers the data present at the IC3 inputs to its outputs.

e. Upon the return of the IC3 clock input to a logical 0 binary, coded data is now retained at the IC3 outputs.

Since IC1 only has a 3 bit capacity (can only encode numbers from 0 to 7) more data is needed for presets higher than 7.

Preset button 8 is coupled by means of CR2 to the 0 input of IC1 which will transfer a 0 code (which is the first 3 lower order bits of an 8 code) on the output of IC1 when depressed.



Both preset buttons 8 and 9 are diode OR'ed, via CR5 and CR6, and coupled through a delay circuit comprised of R4, R5, and C3 to one input of a cross-coupled latch consisting of IC4 C and D, R6, and R7. The other input of this cross-coupled latch is driven by the IC2 negative going one-shot pulse. The action of this latch is as follows:

Depressing any preset button causes the IC2 one-shot to fire (as described earlier) which sets IC4D pin 11 to a logical 0 and IC4C pin 8 to a logical 1; however, if preset button 8 or 9 is depressed, pin 13 of IC4D will be forced to a logical 0 (through diode OR and delay circuit), therefore, before the preset button can be released, the one-shot pulse will have returned to a logical 1. This action reverses the output status of the latch.

Summarizing the IC4C and D latch function:

a. For all presets except 8 or 9, IC4D pin 11 will be set to a logical 0 and IC4C pin 8 at a logical 1.

b. For presets 8 or 9, IC4D pin 11 will be set to a logical 1 and IC4C pin 8 at a logical 0. Preset buttons 10 through 14, rather than having their common side tied to ground (as is the case for buttons 1 through 9), are connected through the base emitter junction of Q1 to ground. Note that the base emitter junction drop of Q1 does not affect the operation of the IC1 input (IC1 input functions the same as if presets 10 through 14 were tied to ground). Depressing any preset button from 10 to 14 causes input current from IC1 to flow through the depressed button and through the base emitter junction of Q1, turning Q1 on and pulling its collector to ground (logical 0). There is now a piece of data which tells us whenever a preset button from 10 to 14 is depressed. This data is applied to and retained at IC3 in the same manner as the data from IC1 as described earlier.

Preset buttons 10 through 14 are also connected to the 0 through 4 inputs of IC1 respectively (preset button 10 to IC1 input 0 and so forth). From this information, notice that IC1, with the exception of presets 8 and 9, will transfer the binary code for the units digit of the preset depressed. For instance, depressing preset 2 will produce a 2 code on the IC1 output, depressing preset 12 will produce a 2 code, depressing preset 13 will produce a 3 code and so forth. Presets 8 and 9 are exceptions because they require an additional bit (IC1 has only 3 output lines and presets 8 and 9 require 4). The first 3 bits are transferred by IC1 and the remaining bit (highest order of "8" line) is stored at the IC4C and D latch as described above.

Summarizing the data stored:

a. IC3 A, B, and C outputs retain data in binary for the units digit of the preset, except only the 3 lowest order bits for presets 8 or 9.

b. IC4C and D latch retains the highest order ("8" line) bit data for presets 8 and 9 (combining this data with data from IC1 output will yield the complete code for presets 8 and 9).

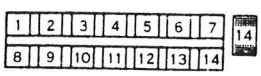
c. IC3D output is a logical 0 for presets 10 through 14 and a logical 1 for presets 1 through 9.

IC6 is a seven segment decoder and driver which converts the binary coded information on its inputs to the proper logic levels to drive the units readout (L1 No. 1). As described above, the complete binary data for the units digit is contained at the IC3 A, B, and C outputs and the IC4C and D latch output. Because IC6 has active high inputs, its A, B, and C inputs are driven from the $\overline{A}$, $\overline{B}$, and $\overline{C}$ outputs of IC3 which follow the logic levels of the A, B, and C outputs only inverted. There is now all the data required to display the units digit.

The tens digit (L1 No. 2) is driven by Q2 whose base is tied to the $\overline{D}$ output of IC3. As described earlier, the D output of IC3 (which is simply the inversion of $\overline{D}$) will be at a logical 0 (ground) for presets 10 through 14, making $\overline{D}$ a logical 1 (positive), therefore, turning Q2 on displays a 1 for the units digit.

The four outputs from IC5 follow the data at the A, B, and C, and D outputs of IC3 only inverted with the exception of presets 8 and 9 where the pin 8, 3 and 6 outputs are forced to a logical 1. This was done to avoid codes being sent to board 9 which would result in inaccurate preset decoding. IC4A and B gates are open collector OR'ed and develop the logic status as indicated in the attached truth table.

Not previously mentioned in this description is the purpose of the delay circuit consisting of R4, R5, and C3. The digital circuit would function correctly without this delay, but slowing down this switching function helps reduce clicks from coupling into the audio output.



The RP1 output is used on the LEFT HAND CONTROL board to return various switching functions to their preset state whenever a preset button is depressed.

The SQUELCH output follows the EO output from IC1 through diode CR4 and is used on board 9 to suppress switching transitions from showing up in the audio output as clicks.

SECTION 8
BOARD 13
POWER SUPPLY

8.1 POWER SUPPLY SUBASSEMBLY CIRCUIT DESCRIPTION - IDENTIFIED WITH MOOG LOGO ON PRINTED CIRCUIT BOARD

The Moog power supply is used on Polymoog Synthesizers above serial numbers 3200 (approximately) and on all Polymoog Keyboard units. Primary power is applied through P101, ON-OFF switch S102, 115-230V selector switch S101 and fuses F101 and F102 to power transformer T1. (Refer to Volume II.) The power transformer is designed with two identical 115 VAC primary windings connected in parallel or series, depending on the position of selector switch S101, to allow either 115 or 230 VAC operation. Each of the three independent output windings of T1 is applied to a full wave bridge rectifier and regulator circuit to provide regulated -15, +15 and +5 VDC outputs. The output of each bridge rectifier is filtered by an electrolytic capacitor having a bleeder resistor connected in parallel to remove any residual charge when power is removed from the unit.

The heart of each regulator section is comprised of a 723 integrated circuit consisting of four basic sections; a temperature compensated voltage reference, operational amplifier, current limiter and current amplifier (see Figure 8-1). The voltage reference section of the +15 and +5 VDC supplies produces a stable +7.15 ± 0.36 VDC output at pin 6 which may be used at that level or divided down. The operational amplifier section is used as a linear amplifier to compare a direct or divided reference voltage applied to pin 5 with a divided sample of the power supply output voltage applied to pin 4. The current amplifier section amplifies the small current obtained from the output of the operational amplifier section and is used as an emitter follower to drive external transistors from pin 10. The current limiter section, when connected to external circuitry, acts to limit or reduce the current available to the current amplifier section should a power supply current overload occur.

The output from each bridge rectifier and filter is a considerably higher voltage than the regulated output voltage. Transistors Q1, Q3, Q5 and Q6 are emitter followers acting as electronically variable resistors controlled by the current applied to their bases. Transistors Q2, Q4 and Q7 operate as current amplifiers driving Q1, Q3, Q5 and Q6. The +7.15 VDC voltage reference from pin 6 of the 723 IC is applied to pin 5 (through a divider resistor on the +5 VDC supply) which is the noninverting input to the operational amplifier section of the IC. A voltage divider between the positive sensing terminal and the negative sensing terminal applies a voltage proportional to the output voltage into the inverting input (pin 4) of the operational amplifier to be compared with the reference voltage applied to pin 5. If the output voltage is too high, the voltage at pin 4 will be higher than the voltage at pin 5. This reduces the current into the base of the driver transistor in turn reducing the current into the base of the pass transistor causing the output voltage to drop to the correct level. If the output voltage is too low, the opposite action occurs.

Two types of overcurrent protection provided include a constant current overload protection used on the + and -15 volt outputs and a foldback overload protection used on the +5 volt output. On the + and -15 volt outputs, resistors R6 and R17 are in series with the output. The current limit transistor in the 723 IC is connected to this resistor so that if the voltage drop of this resistor exceeds 0.6 volt due to excessive output current, this transistor conducts to prevent any further increase in the output current. When this point is reached, the output voltage will start to drop. The foldback overload protection used in the +5 volt section of the power supply operates by sensing both voltage and current. An overload is first sensed by the combined drop across the base-emitter junction of Q5 and the drop across R31. When the combined drop exceeds approximately 1.2 volts, the current limit transistor in the IC starts to conduct causing the output voltage to begin to drop. When this happens, the voltage drop across the divider becomes less causing the current limit to conduct even more. As a result of this regenerative action, the short circuited current of the power supply is much less than the rated full load current.

Variable resistors R8, R19 and R33 allow for individual adjustment of each output voltage. Resistors R10, R21 and R35 and diodes CR6 and CR13

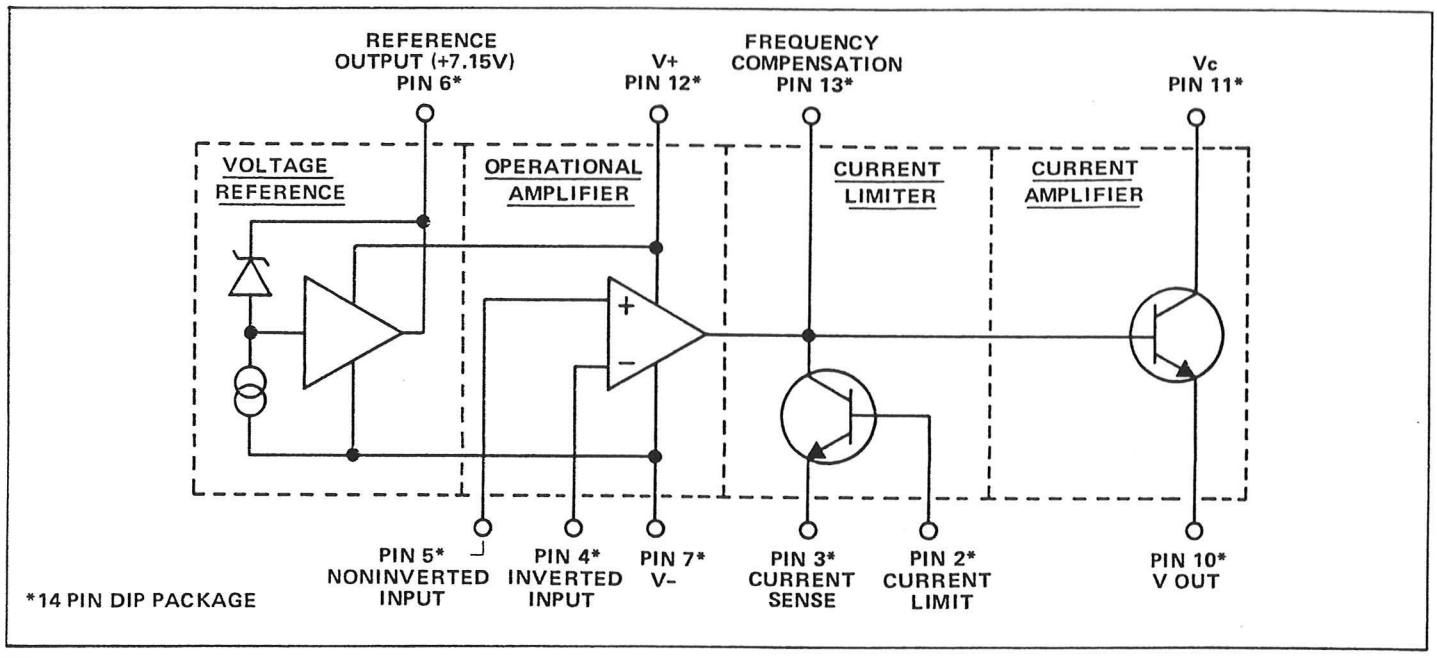

FIGURE 8-1 MOOG VOLTAGE REGULATOR INTEGRATED CIRCUIT (723 DIP PACKAGE)

prevent the outputs from rising to excessive levels should one of the sensing leads accidentally become disconnected. Diodes CR7, CR14 and CR20 across each output protect its output from accidental application of a reversed voltage to its output terminals. Capacitors C3, C6 and C9 provide a low dynamic impedance for each output.

8.2 POWER SUPPLY SUBASSEMBLY CIRCUIT DESCRIPTION – IDENTIFIED WITH FARATRON LOGO (Serial Numbers Below Approximately 3677)

Primary power is applied through P101, ON-OFF switch S102, 115-230V selector switch S101 and fuses F101 and F102 to power transformer T601. (Refer to Volume II). The power transformer is designed with two identical 115 VAC primary windings connected in parallel or series, depending on the position of selector switch S101, to allow either 115 or 230 VAC operation. Each of the three independent output windings of T601 is applied to a full wave bridge rectifier and regulator circuit to provide regulated -15, +15 and +5 VDC outputs. The output of each bridge rectifier is filtered by an electrolytic capacitor having a bleeder resistor connected in parallel to remove any residual charge when power is removed from the unit.

The heart of each regulator section is comprised of a 723 integrated circuit consisting of four basic sections; a temperature compensated voltage reference, operational amplifier, current limiter and current amplifier (see Figure 8-2). The voltage reference section of the +15 and +5 VDC supplies produces a stable +7.15 ±0.36 VDC output at pin 4 which may be used at that level or divided down. The operational amplifier section is used as a linear amplifier to compare a direct or divided reference voltage applied to pin 3 with a divided sample of the power supply output voltage applied to pin 2. The current amplifier section amplifies the small current obtained from the output of the operational amplifier section and is used as an emitter follower to drive external transistors from pin 6. The current limiter section, when connected to external circuitry, acts to limit or reduce the current available to the current amplifier section should a power supply current overload occur.

The output from each bridge rectifier and filter is a considerably higher voltage than the regulated output voltage. Transistors Q1, Q4, Q7 and Q8 are emitter followers acting as electronically variable resistors controlled by the current applied to their bases. Transistors Q2, Q5 and Q9 operate as current amplifiers driving Q1, Q4, Q7 and Q8. The +7.15 VDC voltage reference from pin 4 of the 723 IC is applied to pin 3 (through a divider resistor on the +5 VDC supply) which is the noninverting input to the operational amplifier section of the IC. A voltage divider between the positive sensing terminal and the negative sensing terminal applies a voltage proportional to the output voltage into the inverting input (pin 2) of the operational amplifier to be compared with the refer-

ence voltage applied to pin 3. If the output voltage is too high, the voltage at pin 2 will be higher than the voltage at pin 3. This reduces the current into the base of the driver transistor in turn reducing the current into the base of the pass transistor causing the output voltage to drop to the correct level. If the output voltage is too low, the opposite action occurs.

Two types of overcurrent protection provided include a constant current overload protection used on the + and -15 volt outputs and a foldback overload protection used on the +5 volt output. On the + and -15 volt outputs, resistors R3 and R14 are in series with the output. The current limit transistor in the 723 IC is connected to this resistor so that if the voltage drop of this resistor exceeds 0.6 volt due to excessive output current, this transistor conducts to prevent any further increase in the output current. When this point is reached, the output voltage will start to drop. The foldback overload protection used in the +5 volt section of the power supply operates by sensing both voltage and current. An overload is first sensed by the combined drop across the base-emitter junction of Q7 and the drop across R27. When the combined drop exceeds approximately 1.2 volts, the current limit transistor in the IC starts to conduct causing the output voltage to begin to drop. When this happens, the voltage drop across the divider becomes less causing the current limit to conduct even more. As a result of this regenerative action, the short circuited current of the power supply is much less than the rated full load current.

Variable resistors R8, R19 and R33 allow for individual adjustment of each output voltage. Resistors R6, R17 and R18 and diodes CR19 and CR20 prevent the outputs from rising to excessive levels should one of the sensing leads accidentally become disconnected. Diodes CR6, CR12 and CR18 across each output protect its output from accidental application of a reversed voltage to its output terminals. Capacitors C3, C6 and C9 provide a low dynamic impedance for each output.

8.3 POWER SUPPLY SUBASSEMBLY GENERAL SERVICING AND ADJUSTMENT

The -15, +15 and +5 VDC outputs of the power supply subassembly must be checked first and adjusted to their nominal values within 10 millivolts if necessary prior to any equipment servicing (refer to Table 8-1). The most common anticipated problems related to the power supply subassembly are open rectifier diodes and transistors.

8.4 POWER SUPPLY SUBASSEMBLY REMOVAL

a. If it is necessary to remove a component, unplug the 15-pin main power supply connector from the top of the board and three connectors located at the bottom of the board with blue, gray and green wires.

b. Remove three black Phillips head screws which pass through the heat coupling plate at the bottom of the supply board into the rear panel extrusion.

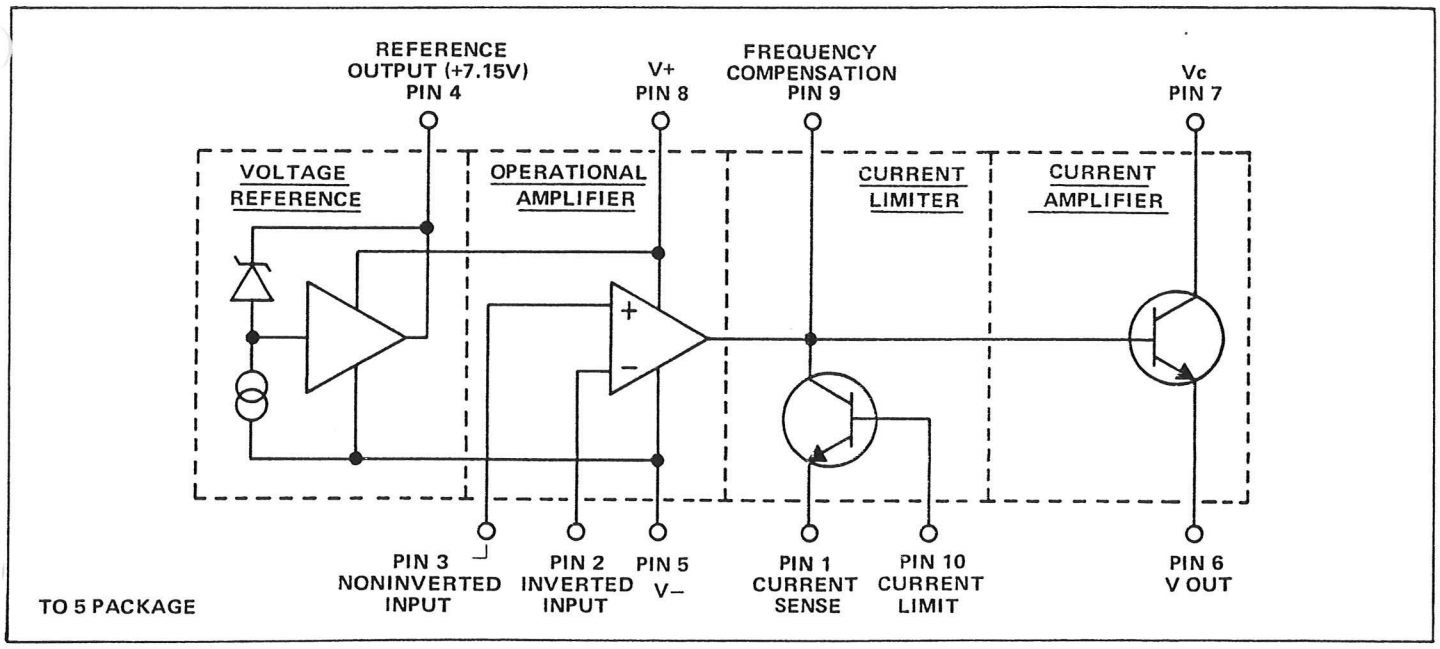

FIGURE 8-2 VOLTAGE REGULATOR INTEGRATED CIRCUIT - FARATRON SUPPLY

c. Remove four nuts on screws attached to standoffs at the top of the board and pull board slightly forward and up out of the unit.

> **CAUTION**
> Extreme caution must be used when remounting the power supply board as it is very important to insure no particles are trapped between the heat coupler plate mounted to the board and the rear panel extrusion. Even very small particles can prevent proper heat transfer from the heat coupler plate to the extrusion.

8.5 POWER SUPPLY SUBASSEMBLY TROUBLESHOOTING

Troubleshoot the power supply subassembly using Tables 8-2 or 8-3, the circuit description, (paragraphs 8.1 or 8.2) and part location and schematic diagrams in Volume II. Note that voltage levels displayed on the schematic diagrams are not absolute values as readings may vary between units. Once the problem is localized, check the suspected part by direct substitution if possible. Otherwise use a voltmeter or oscilloscope to determine the malfunctioning part. Note the color code on the power supply schematics. This is for +15V and +5V parts and is used throughout the instrument harnessing.

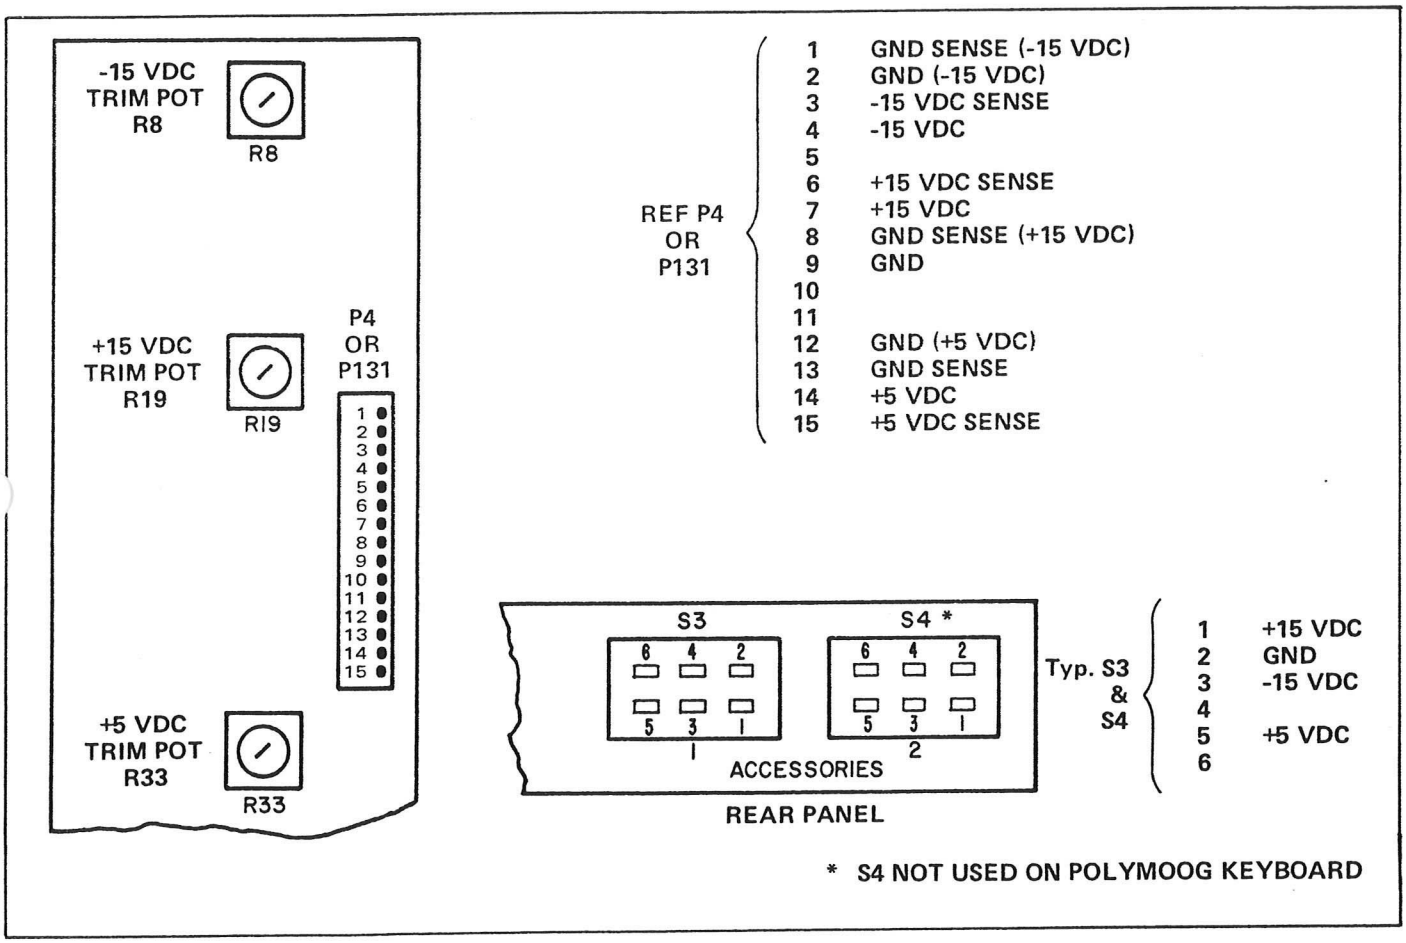

FIGURE 8-3 POWER SUPPLY ASSEMBLY ADJUSTMENT CONTROLS AND OUTPUTS

TABLE 8-1

POLYMOOG AND POLYMOOG KEYBOARD POWER SUPPLY VOLTAGE ADJUSTMENT AND TROUBLESHOOTING

STEP	TEST AND ADJUSTMENT	CORRECTIVE ACTION
1	Apply primary power to Polymoog and connect digital voltmeter negative test lead to pin 2 of accessory connector on rear panel and positive test lead to pin 1. Observe digital voltmeter and adjust +15 VDC trim pot R19 on power supply assembly for +15 VDC ± 10 mv. See Figure 8-3.	If proper voltage is present, proceed to step 2. If output voltage is not present or cannot be adjusted, disconnect power supply output connector and measure voltage between pins 7 (+) and 9 (–). If present, perform step 4. If not present, trouble is in power supply assembly. Refer to Tables 8-2 and 8-3.
2	Reconnect positive test lead to pin 5 of accessory connector. Observe digital voltmeter and adjust +5 VDC trim pot R33 on power supply assembly for +5 VDC ± 10 mv.	If proper voltage is present, proceed to step 3. If output voltage is not present or cannot be adjusted, disconnect power supply output connector and measure voltage between pins 14 (+) and 12 (–). If present, perform step 4. If not present, trouble is in power supply assembly.
3	Reconnect positive test lead to pin 2 and negative test lead to pin 3 of accessory connector. Observe digital voltmeter and adjust -15 VDC trim pot R8 on power supply assembly for -15 VDC ± 10 mv.	If proper voltage is present, power supply assembly is operating properly. If output voltage is not present or cannot be adjusted, disconnect power supply output connector and measure voltage between pins 4 (–) and 2 (+). If present, perform step 4. If not present, trouble is in power supply assembly.
4	Reconnect power supply output connector and digital voltmeter test leads to pins on accessory connector where proper voltage was not available. **CAUTION:** If power supply failed by going out of regulation causing high voltages to be applied throughout the instrument, there are voltage suppressors on the Left Hand Control (CL) and Right Hand Control (CR) printed circuit boards that will short. These are 15 kilowatt Zener diodes identified as CP1 (Circuit Protector 1) on the CR board and CP1 through CP3 on the CL board. These devices must be replaced if shorted. If the instrument is operated without the circuit protectors in place, severe damage to the associated semiconductors and integrated circuits (CMOS, TTL) could result.	Monitor digital voltmeter and sequentially disconnect power supply input connectors on TR. (P91), TC (P88), TL (P71), MBL (P41 and P42), MBM (P51 and P52), MBH (P61 and P62) and DIV (P325) printed circuit boards until voltage indication appears (shorted board located). Troubleshoot or repair board as outlined in its applicable section. If voltage indication still is not present, trouble is in CL (P107), Mode (P112) or CR (P111) Polymoog printed circuit boards or cable harness. If no voltage indication is present on Polymoog Keyboard, trouble is in CLP1010 or Master Voice Keyboard P106 printed circuit boards or wiring harness.

TABLE 8-2
MOOG POWER SUPPLY SUBASSEMBLY TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Loss of all output voltages	Power source, P101, S101, S102, F101, F102 and T1
Loss of -15V output voltage	Voltage buss external to power supply shorted to common, P132, CR1 thru CR4, Q1, Q2, IC1, R8, P131 and C3
Voltage at pin 6 of IC1 is not -7.85 ± 0.39V or voltage at pin 10 is less than +1.62V	IC1, C1, R2 thru R4, R6 and R10
Loss of -15V output adjustment	R10, R7 thru R9
Excessive -15V output voltage, no voltage control	Q1, Q2 and IC1
Voltage at pin 7 of IC1 is not -7.85 ± 0.39V or voltage at pin 4 is higher than at pin 7	IC1 and C2
Low -15V output voltage	CR1 thru CR4, instrument wiring shorted
Loss of +15V output voltage	Voltage buss external to power supply shorted to common, P133, CR8 thru CR11, Q3, Q4, IC2, R19, P131 and C6
Voltage at pin 6 of IC2 is not +7.15 ± 0.36V or voltage at pin 10 is less than +16.7V	IC2, C4, R13 thru R15, R17, R21, CR12 and C6
Loss of +15V output adjustment	R18 thru R21
Excessive +15V output voltage, no voltage control	Q3, Q4 and IC2
Voltage at pin 7 of IC2 is not +7.15 ± 0.36V or voltage at pin 4 is higher than at pin 7	IC2 and C5
Low +15V output voltage	CR8 thru CR11, instrument wiring shorted
Loss of +5V output voltage	Voltage buss external to power supply shorted to common, P3, CR15 thru CR18, Q5 thru Q7, IC3, R33, P4 and C9
Voltage at pin 6 of IC3 is not +7.15 ± 0.36V or voltage at pin 10 is less than +7.32V	IC3, C7, R35, R24 thru R28, R30, R31, CR19 and C9
Loss of +5V output adjustment	R33 thru R35
Excessive +5V output voltage, no voltage control	Q5 thru Q7 and IC3
Voltage at pin 7 of IC3 is not +4.53 ± 0.23V or voltage at pin 4 is higher than at pin 7	IC3 and C8
Low +5V output voltage	CR15 thru CR18, instrument wiring shorted

TABLE 8-3
FARATRON POWER SUPPLY SUBASSEMBLY TROUBLESHOOTING

PROBLEM	PROBABLE DEFECTIVE COMPONENT
Loss of all output voltages	Power source, P101, S101, S102, F101, F102, T601
Loss of -15V output voltage	Voltage buss external to power supply shorted to common, P1, CR1 thru CR4, Q1 thru Q3, R8, P4, C3
Voltage at pin 4 of Q3 is not -7.85 ±0.39V or voltage at pin 6 is less than +1.62V	Q3, C1, R2 thru R6, CR5, C3
Loss of -15V output adjustment	R6, R8 thru R10
Excessive -15V output voltage, no voltage control	Q1 thru Q3
Voltage at pin 3 of Q3 is not -7.85 ±0.39V or voltage at pin 2 is higher than at pin 3	Q3, C2
Low -15V output voltage	CR1 thru CR4, instrument wiring shorted
Loss of +15V output voltage	Voltage buss external to power supply shorted to common, P2, CR7 thru CR10, Q4 thru Q6, R19, P4, C6
Voltage at pin 4 of Q6 is not +7.15 ±0.36V or voltage at pin 6 is less than +16.7V	Q6, C4, R13 thru R17, CR11, C6
Loss of +15V output adjustment	R17, R19 thru R21
Excessive +15V output voltage, no voltage control	Q4 thru Q6
Voltage at pin 3 of Q6 is not +7.15 ±0.36V or voltage at pin 2 is higher than at pin 3	Q6, C5
Low +15V output voltage	CR7 thru CR10, instrument wiring shorted
Loss of +5V output voltage	Voltage buss external to power supply shorted to common, P3, CR13 thru CR16, Q7 thru Q10, R33, P4, C9
Voltage at pin 4 of Q10 is not +7.15 ±0.36V or voltage at pin 6 is less than +7.32V	Q10, C7, R18, R24 thru R30, CR17, C9
Loss of +5V output adjustment	R18, R33, R34

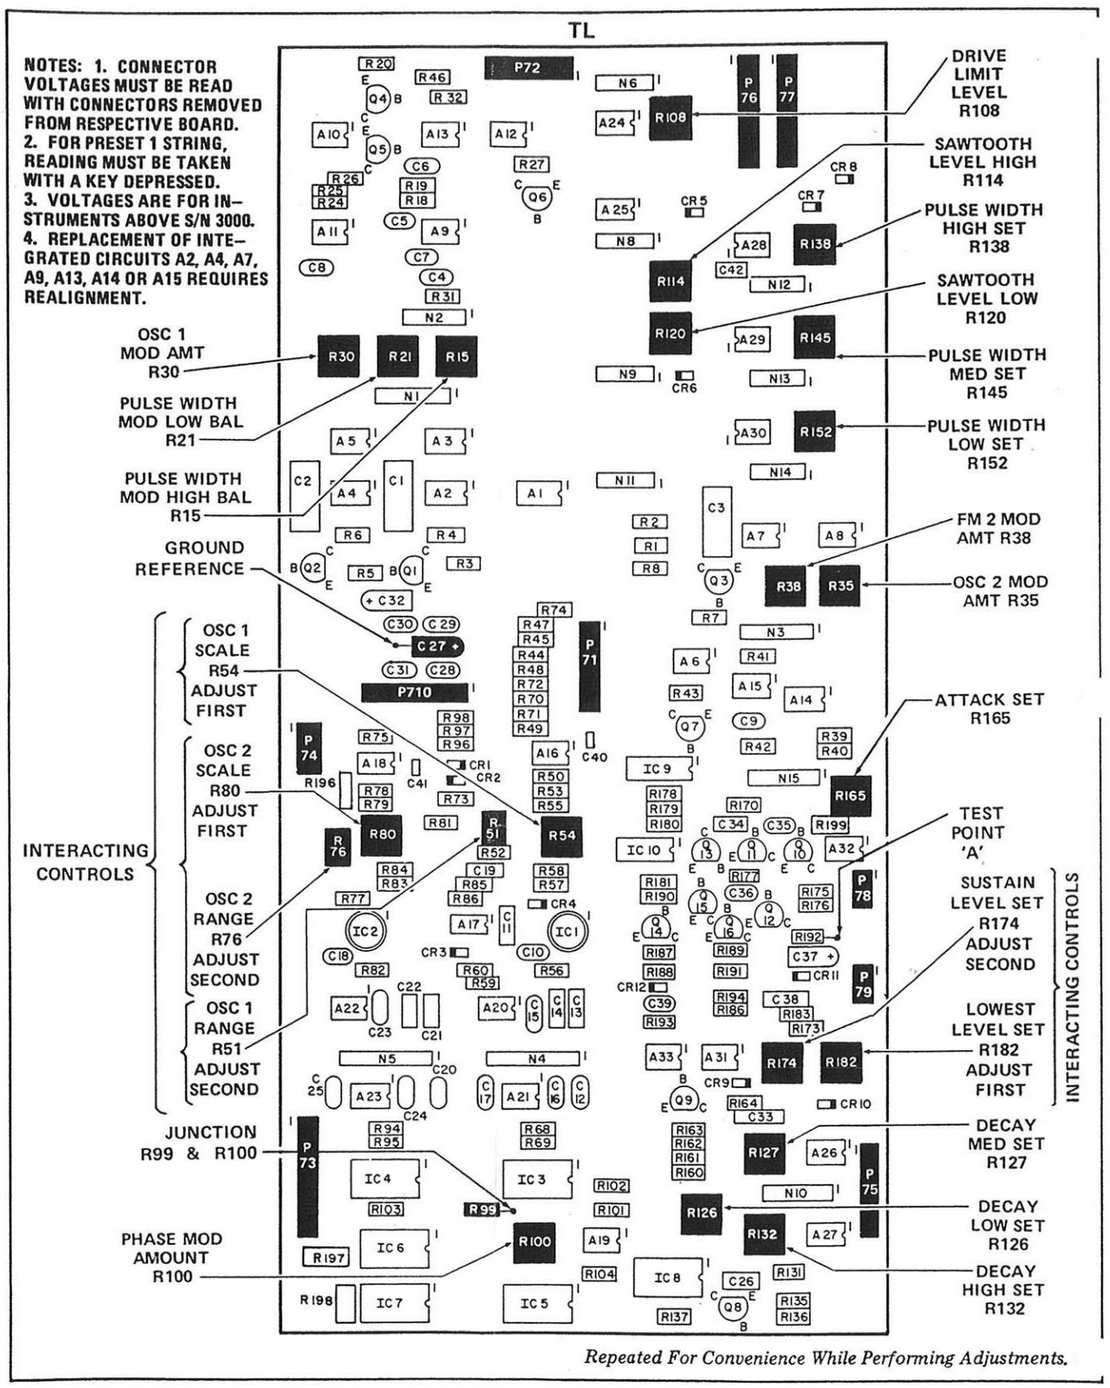
POWER SUPPLY SUBASSEMBLY

NOTES: 1. CONNECTOR VOLTAGES MUST BE READ WITH CONNECTORS REMOVED FROM RESPECTIVE BOARD.
2. FOR PRESET 1 STRING, READING MUST BE TAKEN WITH A KEY DEPRESSED.
3. VOLTAGES ARE FOR INSTRUMENTS ABOVE S/N 3000.
4. REPLACEMENT OF INTEGRATED CIRCUITS A2, A4, A7, A9, A13, A14 OR A15 REQUIRES REALIGNMENT.



Repeated For Convenience While Performing Adjustments.

Factory Service Bulletin

2500 WALDEN AVE. • BUFFALO, NEW YORK 14225 • UNITED STATES
51 NANTUCKET BLVD. • SCARBOROUGH, ONT. M1P 2N6 • CANADA
WAALHAVEN • Z.Z. 48 ROTTERDAM • THE NETHERLANDS

SUBJECT: Polymoog Synthesizer Model 203A
Polymoog Keyboard Model 280A
Polypedal Model 285

NUMBER: 1207 DATE: 11/7

Supercedes:
M101, M101A, M102,
M102A, M103, 702
805, 806, 807, 808

This bulletin provides the procedures and information to update the Polymoog Synthesizer and Polymoog Keyboard to current manufacturing specifications. The information furnished relates to sound, reliability and improved performance.

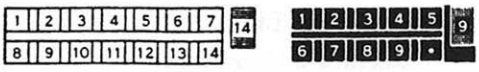
The bulletin is structured to enable the service technician to quickly determine which modifications may be required to update an instrument. Each section is carefully documented and supported with a generous number of clarifying illustrations.

The updates basically fall into one of two categories. First are the preset voicing changes which apply only to Polymoog Synthesizers below serial number 3000. (Each authorized technician should become familiar with the differences in voicing to adequately describe the details of these changes to a prospective customer.) The second category is titled Reliability and Performance Improvement. This section is subdivided into smaller sections, each one covering a board or subassembly. Information common to both the Polymoog Synthesizer and Polymoog Keyboard appears first, followed by specific Synthesizer or Keyboard information. Symbols at the bottom of each page identify information pertaining to the Polymoog Synthesizer or Polymoog Keyboard or both. A serial number reference guide on the next page correlates the modifications and serial numbers.

Service guides and kit information are provided as a convenience at the end of this bulletin.

The Reliability and Performance Improvement Kit contains all parts necessary to update a Polymoog Synthesizer or Polymoog Keyboard. Service Centers may order complete updating kits and replenish parts from the kit as they are used.

Any Polymoog presented for service in the United States may be fully updated according to the Reliability and Performance Improvement modifications as long as the instrument is still in its warranty period. However, warranty consideration varies overseas, therefore check with your local distributor. It is estimated that complete updating may take 8 hours for a Polymoog Synthesizer, 4 hours for updating a Polymoog Keyboard and 1/2 hour for a Polypedal as outlined in this bulletin.



SERIAL NUMBER REFERENCE GUIDE

MODIFICATION OF PRESET VOICING

These modifications level out the volume difference between preset voices on the DIRECT, MODE and VCF Outputs and also update the sound of the presets according to the latest market research as follows:

PRESET VOICE

Preset 1. Strings
MODE OUTPUT - has a fuller bass and the attack and decay time is decreased for more rapid playing styles. VCF OUTPUT - is swept with a slow modulation.

Preset 2. Piano
Has more even dynamics.

Preset 3. Organ
MODE OUTPUT - is less percussive with a slower attack. VCF OUTPUT - the contour sweeps the filter at a slow rate.

Preset 4. Harpsichord
MODE OUTPUT - has a fuller sound with increased bass response in the lower 2 octaves.

Preset 5. Funk
VCF OUTPUT has decreased emphasis which reduces background noise.

Preset 6. Clavinet
Unchanged.

Preset 7. Vibes
Unchanged.

Preset 8. Brass
VCF OUTPUT has less emphasis (WAH).

LOCATION: STRING FILTER PRINTED CIRCUIT BOARD 996-040352-001, (Version 1, Refer to Figure 1).
Change resistor R2 from 43K to 33K and label R3.
Change resistor R3 from 43K to a 0.001 capacitor and label C2.
Remove C2 (500 pf).
Add resistor R2, 82K Ohms from pin 1 to pin 6 of A1 (between newly labeled R3 and R4).

LOCATION: STRING FILTER PRINTED CIRCUIT BOARD 996-040352-001,(Version 2, Refer to Figure 2).
Change resistor R2 from 680K to 82K.

LOCATION: PIANO FILTER PRINTED CIRCUIT BOARD ASSEMBLY 996-040356-001, Refer to Figure 3.
Remove resistor R2, 10K.

LOCATION: ORGAN FILTER PRINTED CIRCUIT BOARD ASSEMBLY, 996-040360-001, Refer to Figure 3A.
Change R5 from 100K to 27K.

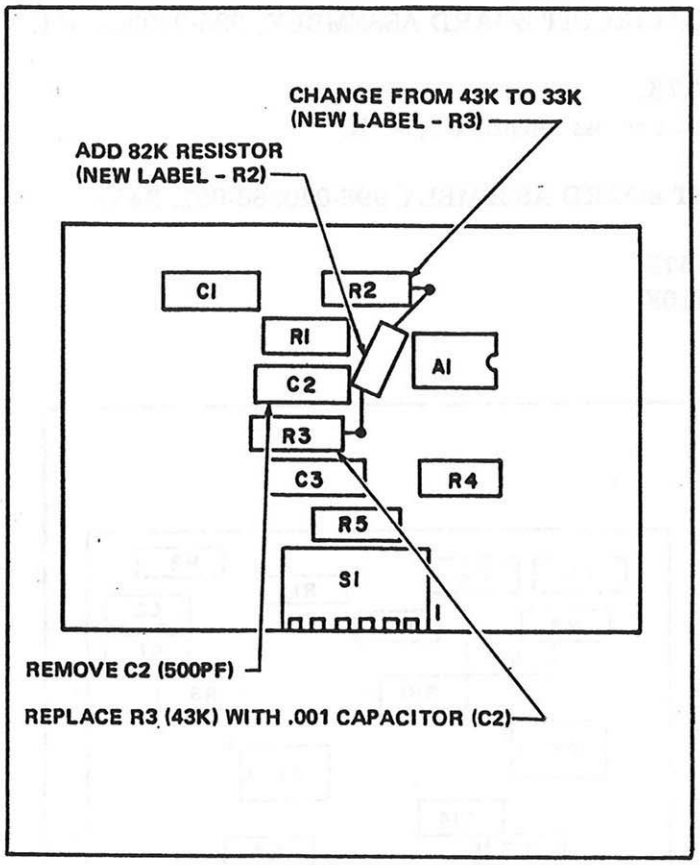

FIGURE 1 MODIFICATION OF STRING FILTER BOARD 1 (VERSION 1) (POLYMOOG)

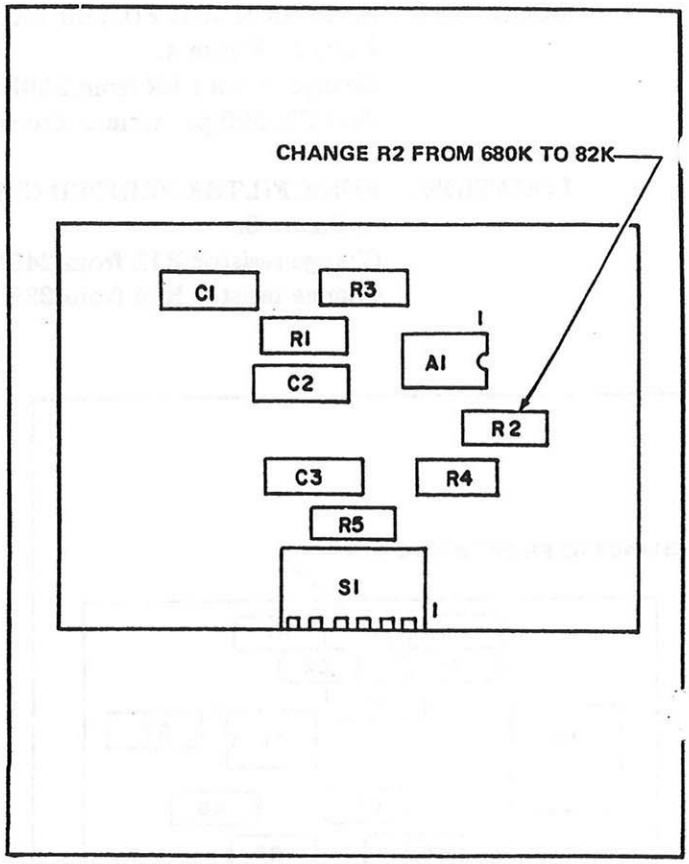

FIGURE 2 MODIFICATION OF STRING FILTER BOARD 1 (VERSION 2) (POLYMOOG)

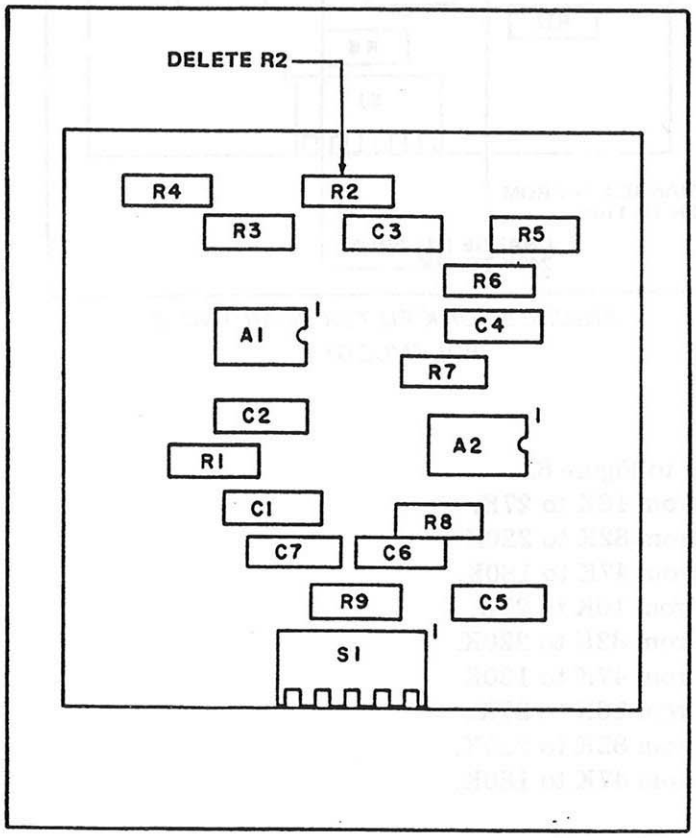

FIGURE 3 PIANO FILTER BOARD NO. 2 (POLYMOOG)

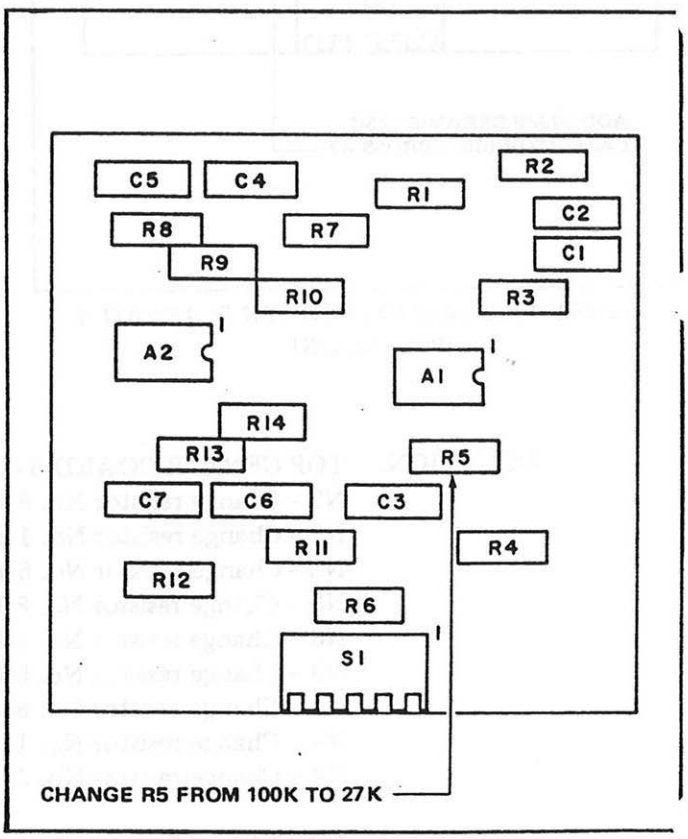

FIGURE 3A ORGAN FILTER BOARD NO. 4 (POLYMOOG)

1207-5

LOCATION: HARPSICHORD FILTER PRINTED CIRCUIT BOARD ASSEMBLY, 996-040364-001, Refer to Figure 4.
Change resistor R2 from 220K to 4.7K.
Add C5, 500 pf ceramic disc capacitor across resistor R7, 47K.

LOCATION: FUNK FILTER PRINTED CIRCUIT BOARD ASSEMBLY 996-040366-001, Refer to Figure 5.
Change resistor R11 from 240K to 47K.
Change resistor R14 from 22K to 110K.

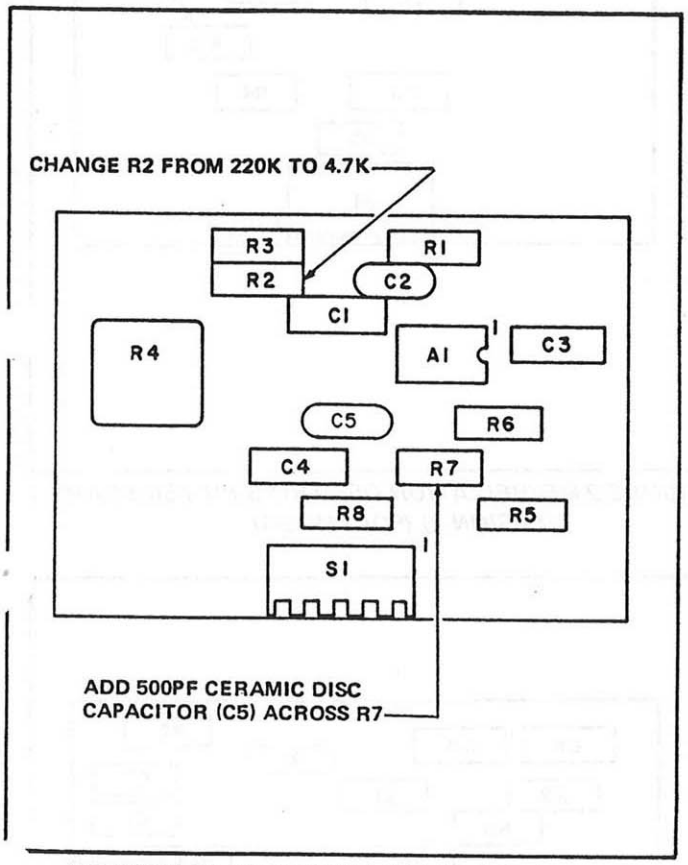

FIGURE 4 HARPSICHORD FILTER BOARD NO. 4 (POLYMOOG)

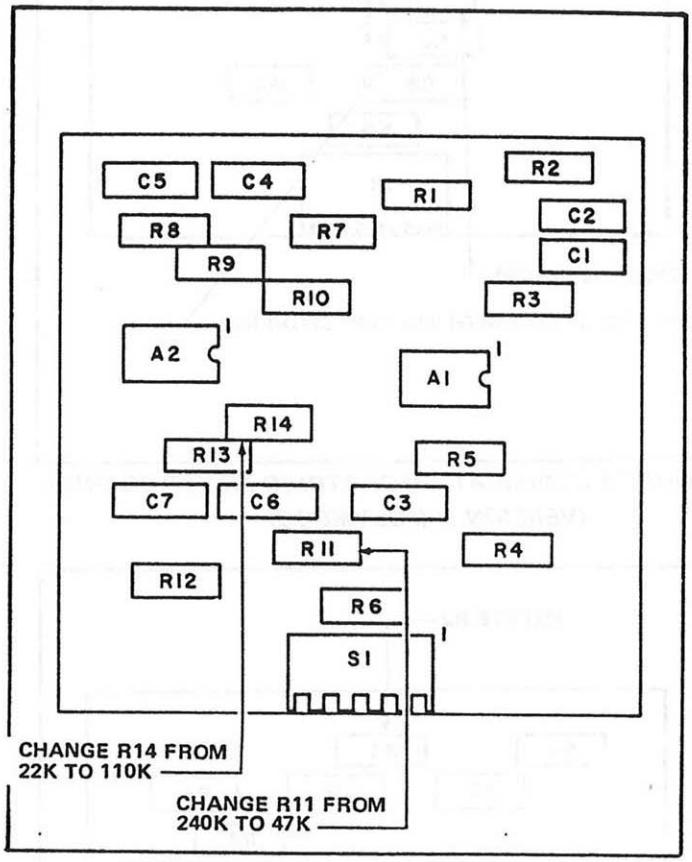

FIGURE 5 FUNK FILTER BOARD NO. 5 (POLYMOOG)

LOCATION: TOP CENTER BOARD 8 - Refer to Figure 6.
N2 - Change resistor No. 8 R21 from 10K to 27K.
N2 - Change resistor No. 1 R28 from 82K to 220K.
N2 - Change resistor No. 5 R25 from 47K to 180K.
N3 - Change resistor No. 8 R29 from 10K to 27K.
N3 - Change resistor No. 1 R36 from 82K to 220K.
N3 - Change resistor No. 5 R33 from 47K to 180K.
N4 - Change resistor No. 8 R37 from 10K to 27K.
N4 - Change resistor No. 1 R44 from 82K to 220K.
N4 - Change resistor No. 5 R41 from 47K to 180K.

LOCATION: TOP RIGHT BOARD 9 - Refer to Figure 7.
N5 - Change resistor No. 7 R146 from 10K to 27K.

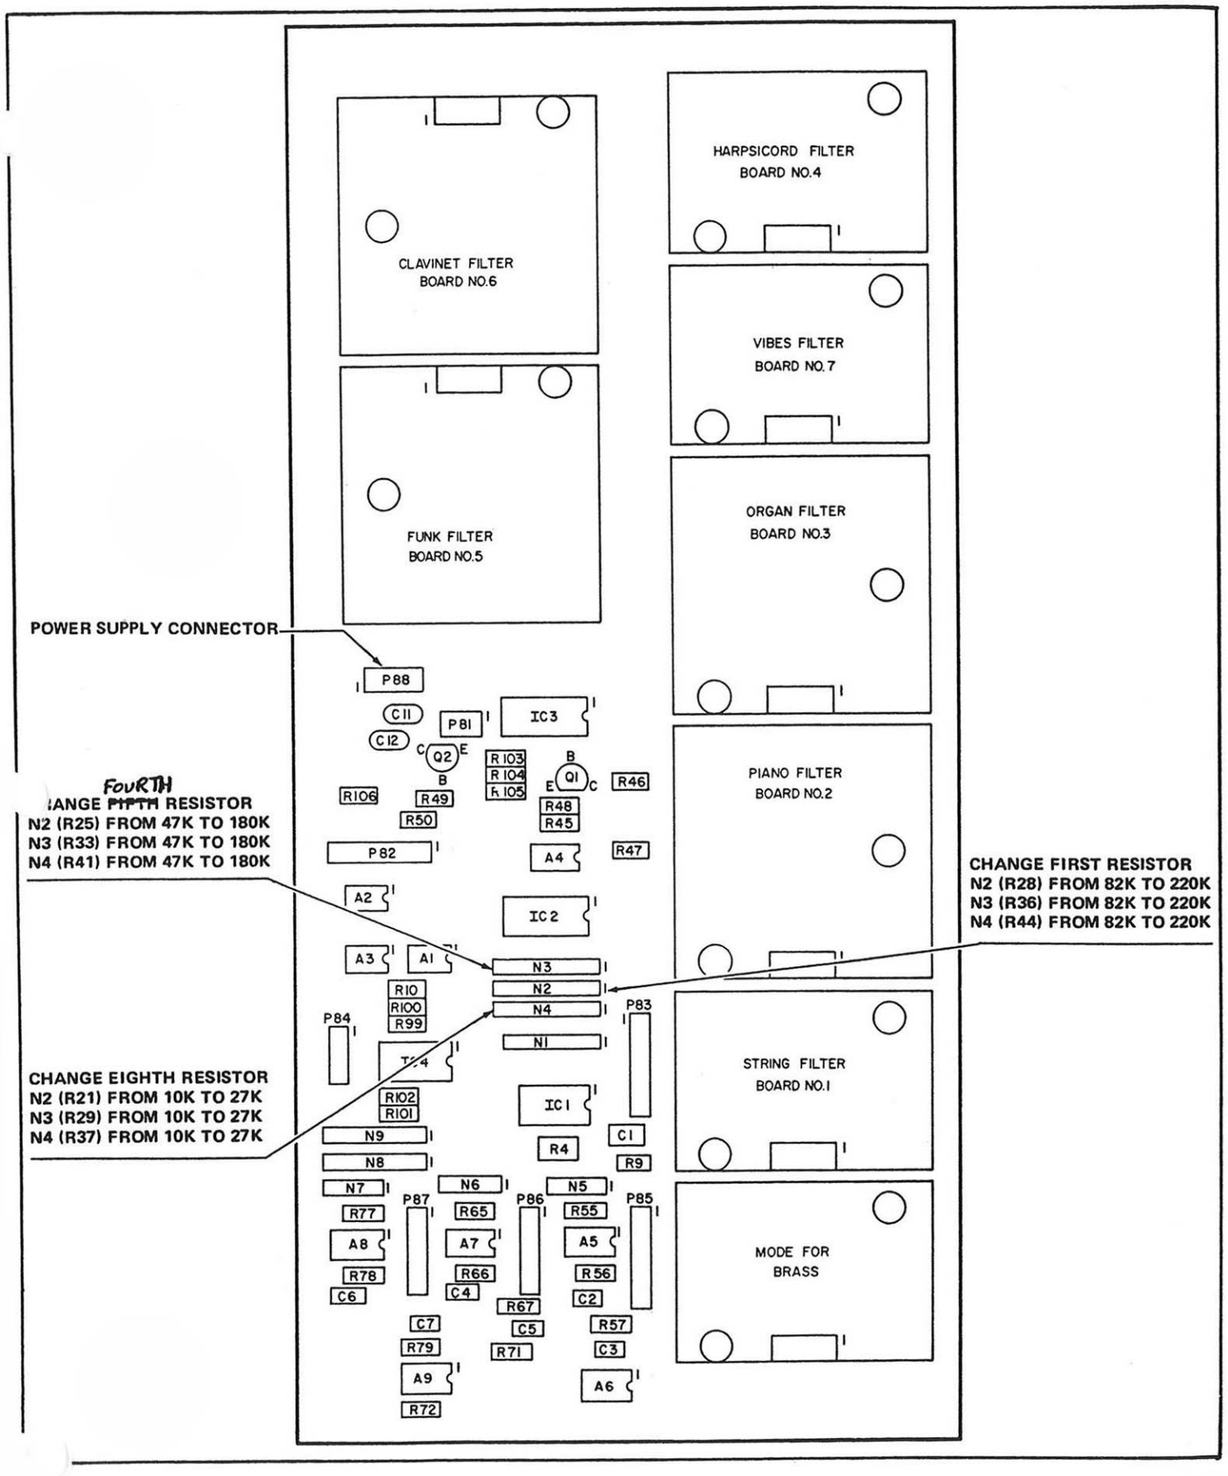

FIGURE 6 FIXED AND VARIABLE RESONANT FILTERS PRINTED CIRCUIT TC BOARD 8 (POLYMOOG)

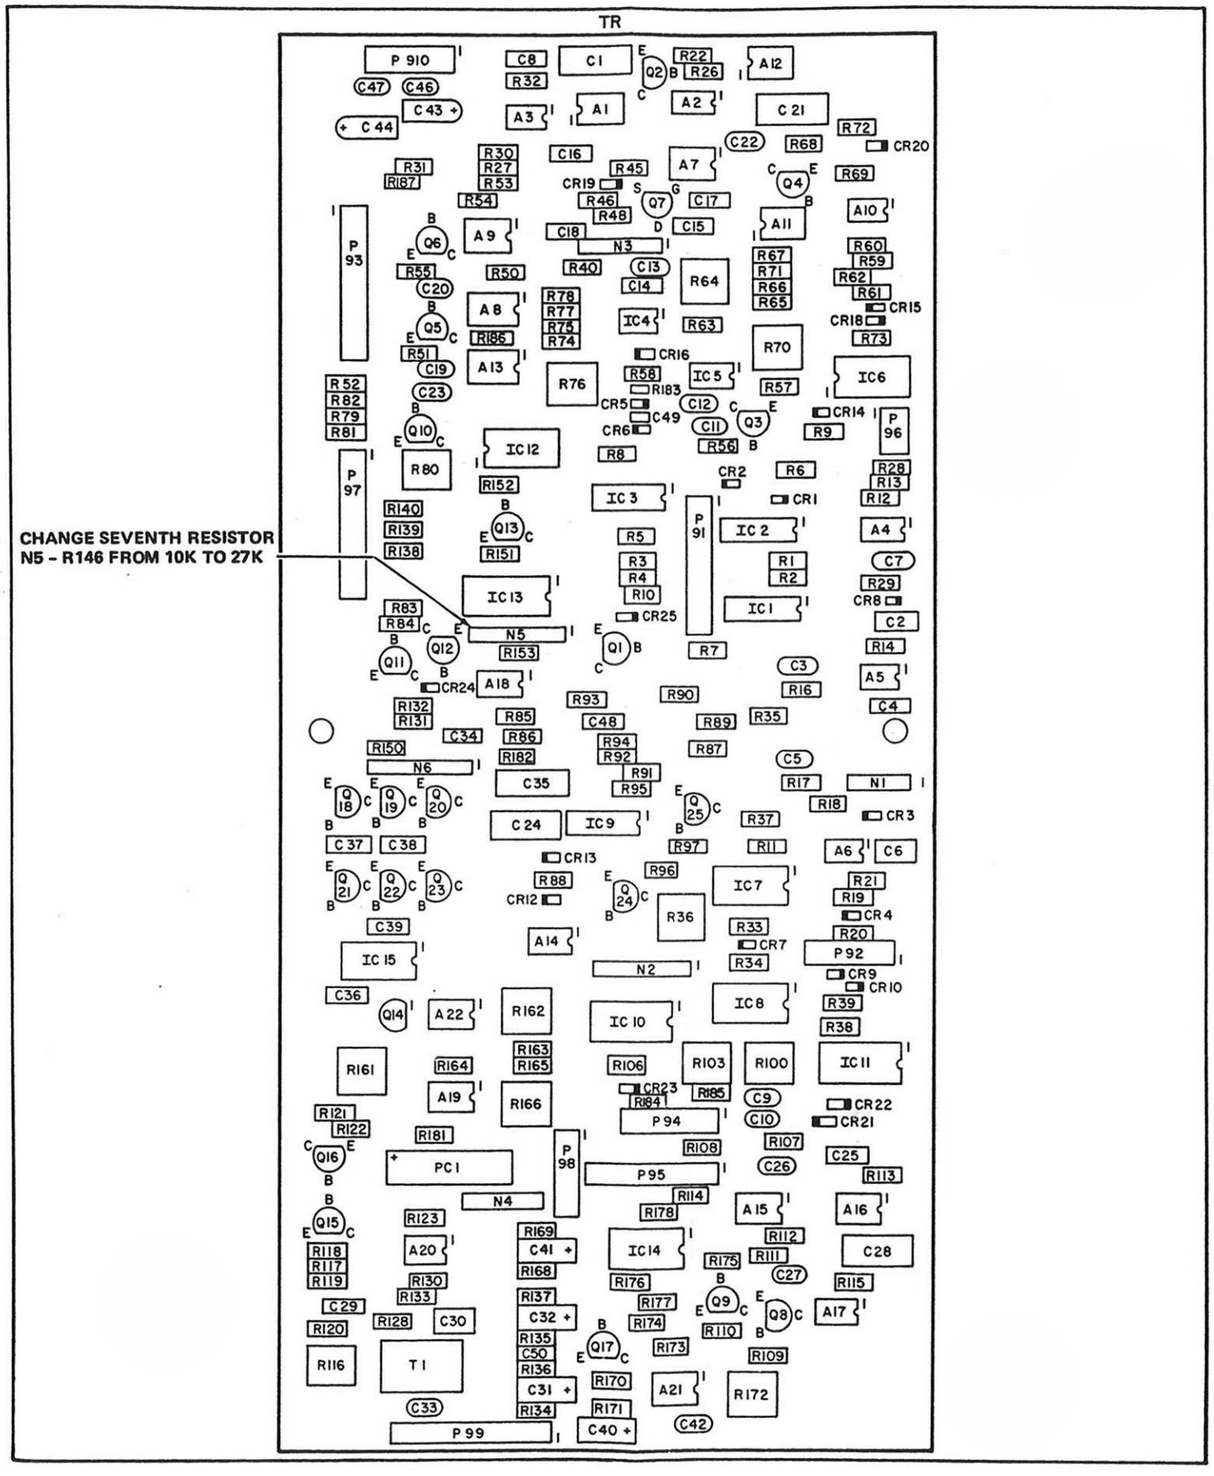

FIGURE 7 VOLTAGE CONTROLLED FILTER AND KEYBOARD CIRCUIT PRINTED CIRCUIT TR BOARD 9 (POLYMOOG)

LOCATION: RIGHT HAND CONTROL BOARD 11 - Refer to Figure 8.

N1 - Add R1, 33K.
N2 - Add R1, 3.3 Megohm.
N3 - Add R1, 62K.
N4 - Add R1, 20K.
N4 - Remove R8, 27K.
N4 - Change R5 from 12K to 15K.
N7 - Change R3 from 9.1K to 1 Megohm.
N8 - Change R3 from 47K to 1 Megohm.
N9 - Change R3 from 16K to 27K.
N9 - Remove R1, 12K.
N13 - Change R2 from 200K to 130K.
N14 - Change R1 from 33K to 120K.
N14 - Change R5 from 68K to 56K.
N15 - Change R1 from 33K to 110K.
N15 - Change R5 from 68K to 56K.
N17 - Change R1 from 150K to 110K.
N17 - Change R3 from 220K to 130K.

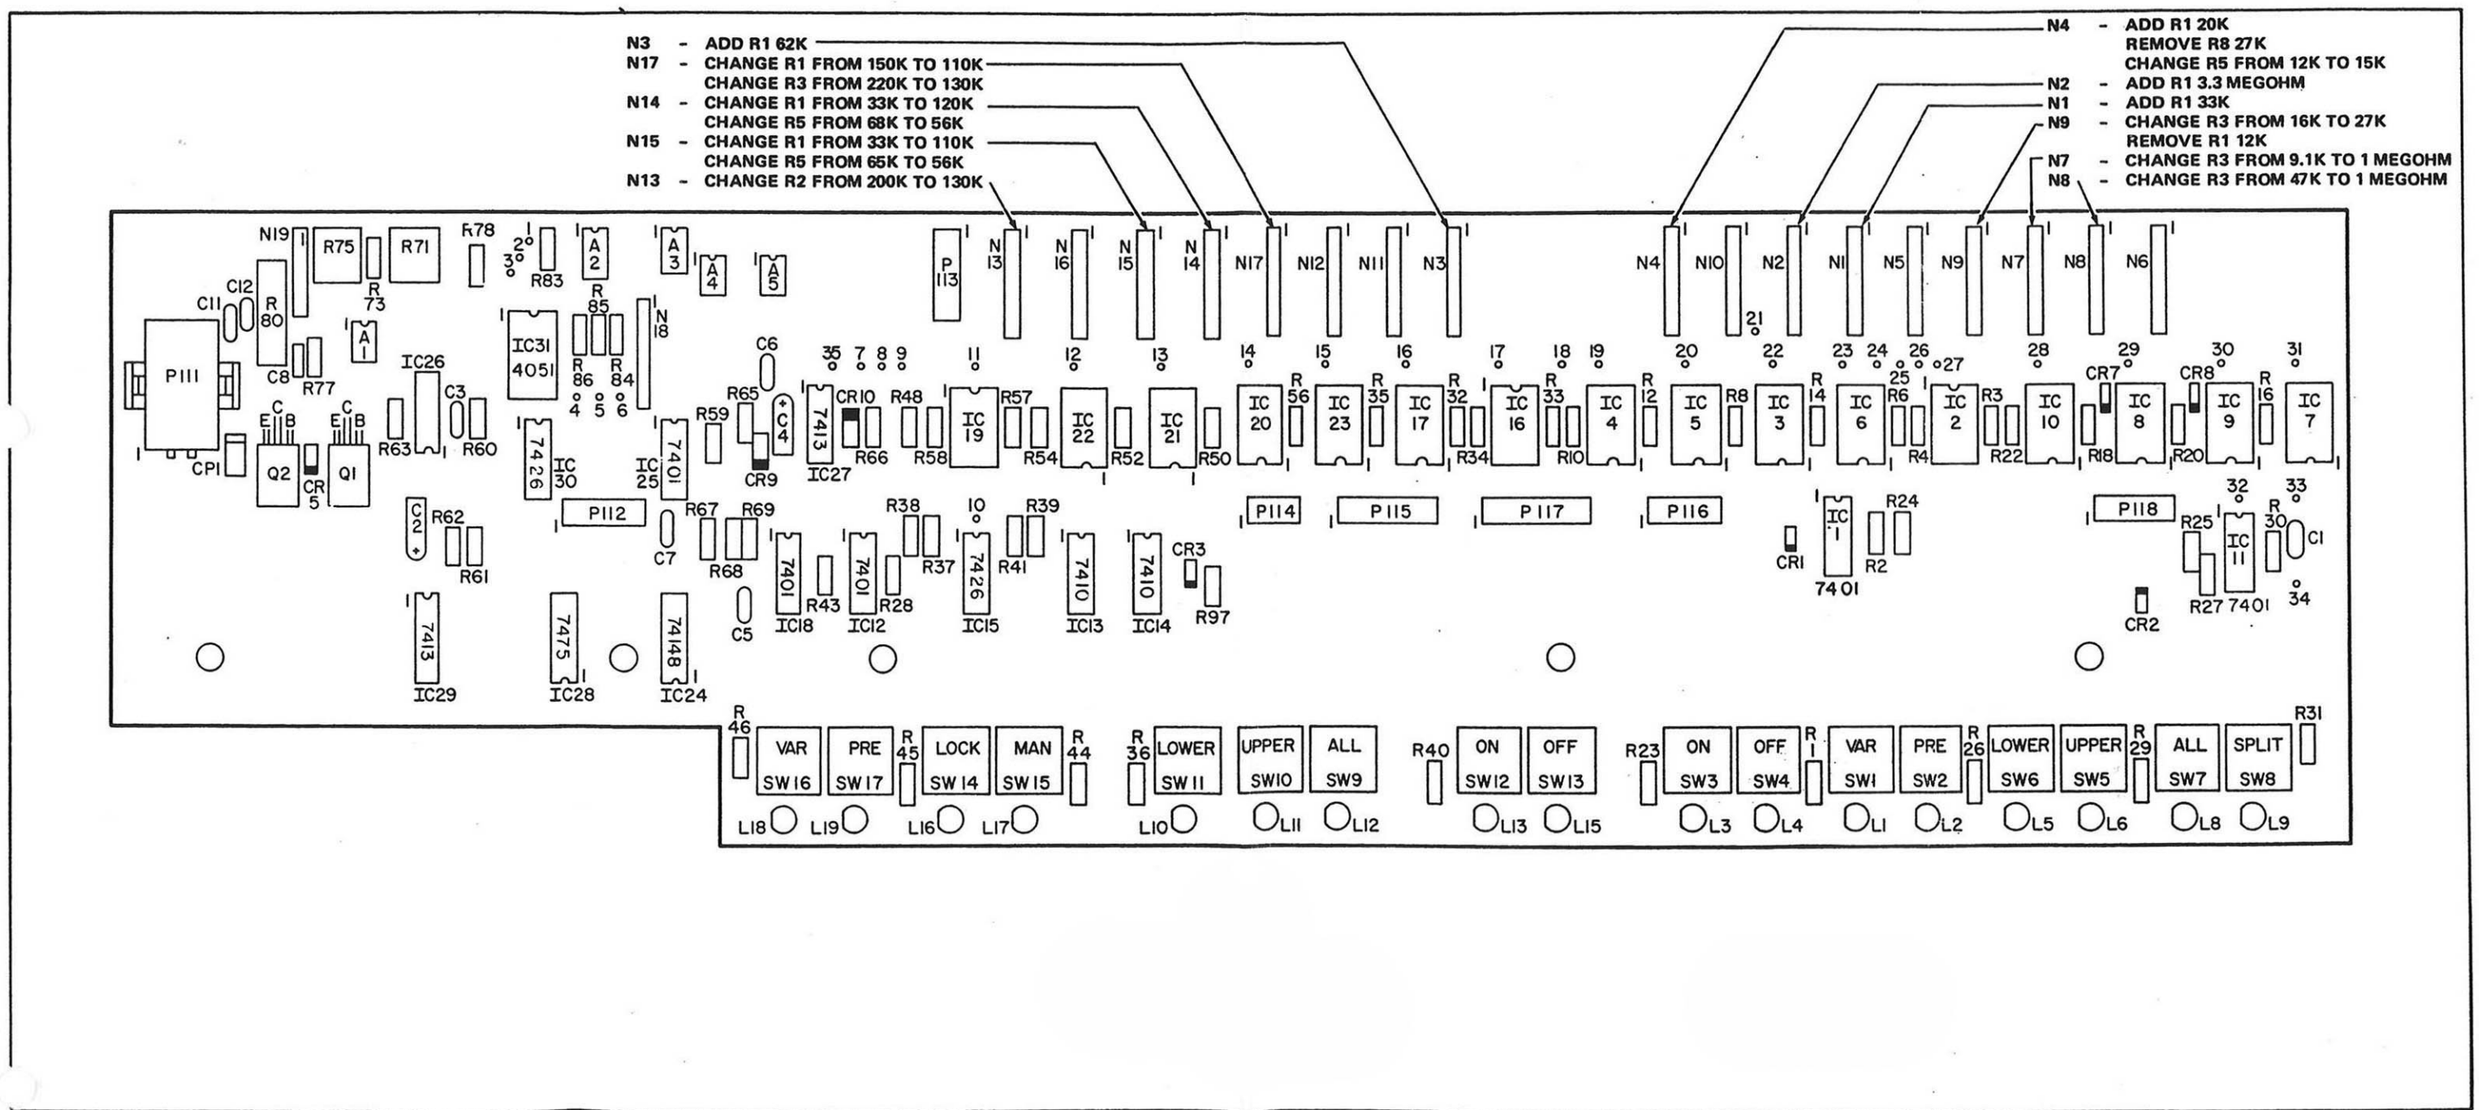

FIGURE 8 RIGHT HAND CONTROL AND MASTER PRESET PRINTED CIRCUIT CR BOARD 11 (POLYMOOG)

RELIABILITY AND PERFORMANCE IMPROVEMENT

LOCATION: POWER SUPPLY BOARD 13. Refer to Figure 9.

a. Thermal Coupling Improvement Between Power Supply And Rear Panel Extrusion.

Counter bore 1/2 inch (12.7mm) diameter x 3/32 inch (2.4mm) deep in three (3) places as indicated at heat sink mounting holes. Remove all burrs.

File printed circuit board overhang until flush with the heat sink. On occasion the mounting hardware screw heads may also need filing. In addition, the printed circuit board mounting holes (to the rear panel) may need to be enlarged to allow the power supply to be reseated in a lower position once the overhang has been filed off.

b. Pass Transistor Improvement.

Remove 2N5494 transistors.

Clear the solder from around the transistor mounting pads.

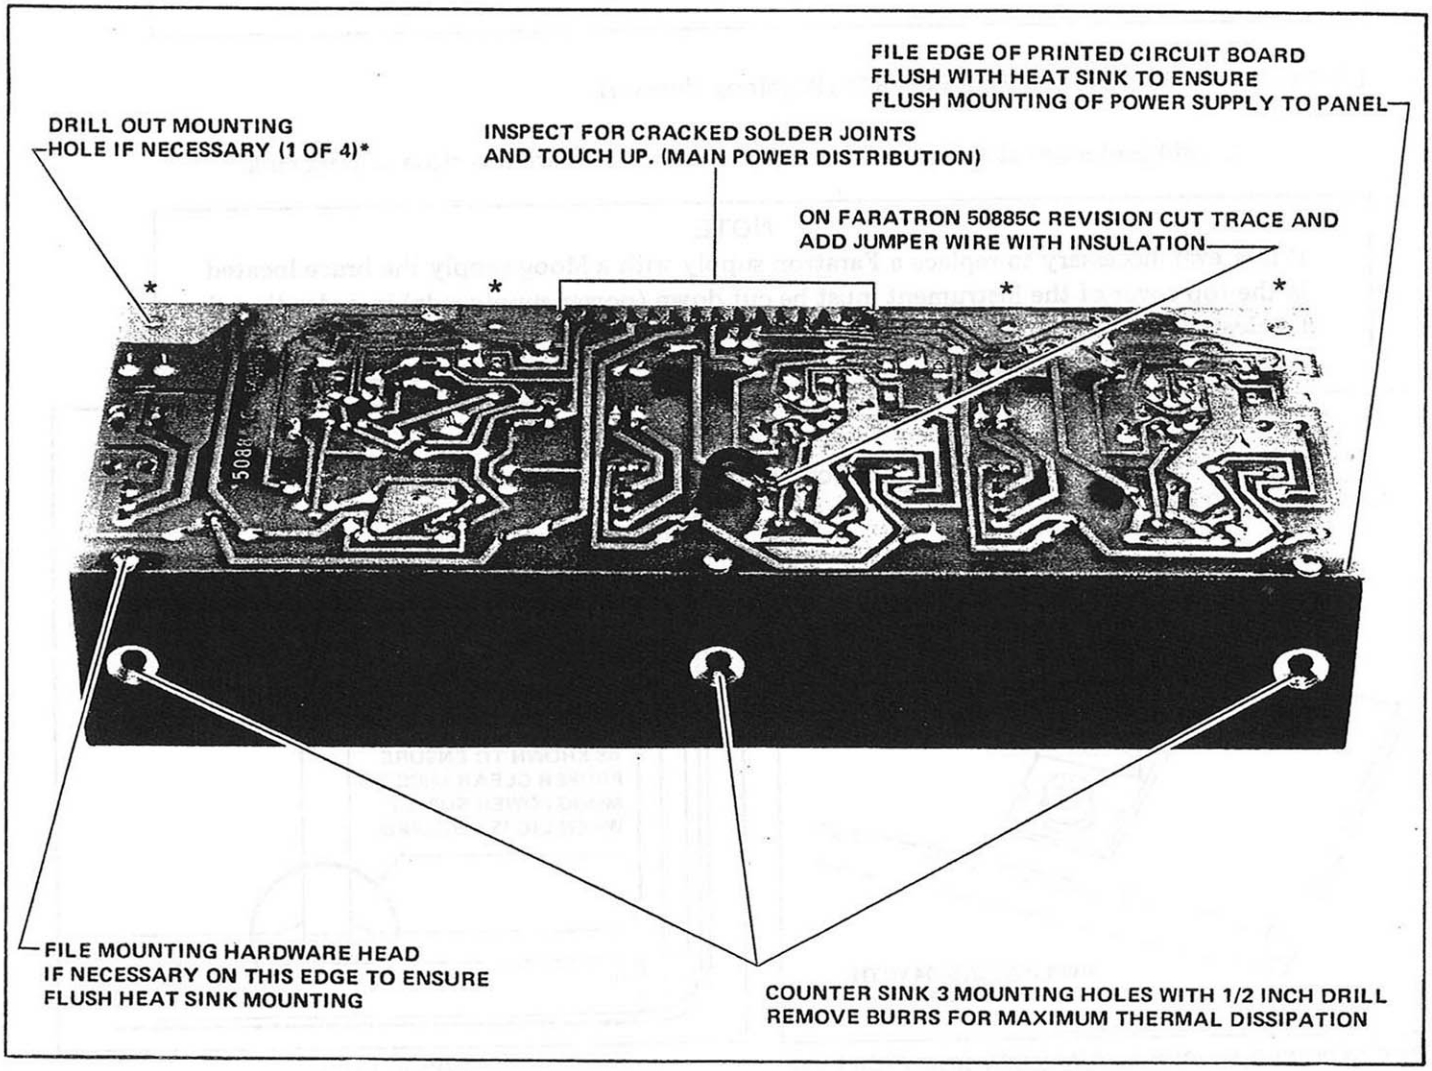

FIGURE 9 POWER SUPPLY PRINTED CIRCUIT BOARD 13
(POLYMOOG AND POLYMOOG KEYBOARD)

Stress relieve replacement transistors as shown in Figure 10. Use a pair of needlenose pliers. Do not make sharp bends in the leads as they will fracture.

Attach TIP41/RCA41 transistors to the heat sink and secure with mounting hardware. Ensure that the insulators are properly seated.

Solder the transistor legs in place.

c. Prevent +15 Volt Supply Over Voltage Condition.

This applies only to Faratron power supply subassembly 50885 C revision as identified with this part number etched on some of the printed circuit boards. Sense diode CR20 not connected according to schematic layout due to improper printed circuit board etch.

Correction - Cut trace and add jumper wire with sleeving.

NOTE

Intermittent or unstable operation of any of the three main power supply voltages may be due to cracked solder joints at the main power supply printed circuit connector P131. Inspect the soldering at all 15 pins and touch up as needed.

LOCATION: POWER SUPPLY BOARD 13. (Moog Version)

a. Add protective sleeving to filter capacitor leads that are too close to heat sink.

NOTE

If it is ever necessary to replace a Faratron supply with a Moog supply the brace located in the top cover of the instrument must be cut down (power supply side) in order that the lid clears the supply subassembly. See Sketch.

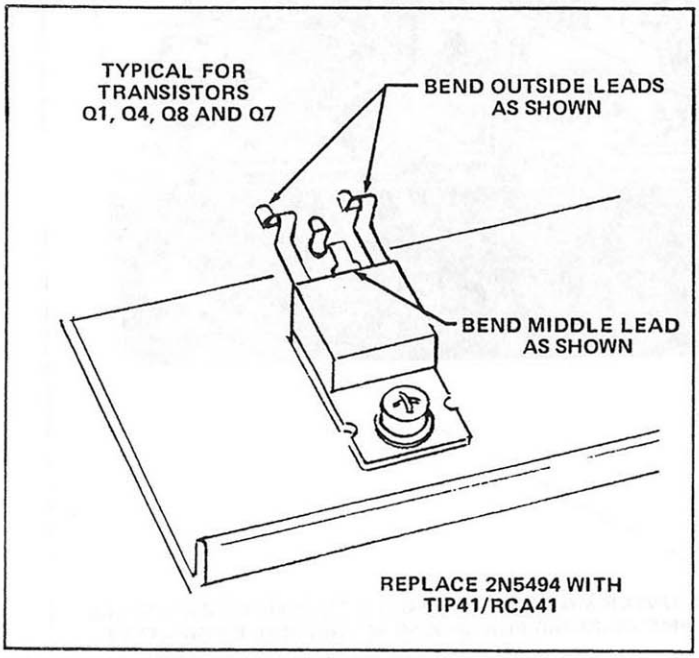

FIGURE 10 POWER SUPPLY TRANSISTOR MODIFICATION (POLYMOOG AND POLYMOOG KEYBOARD)

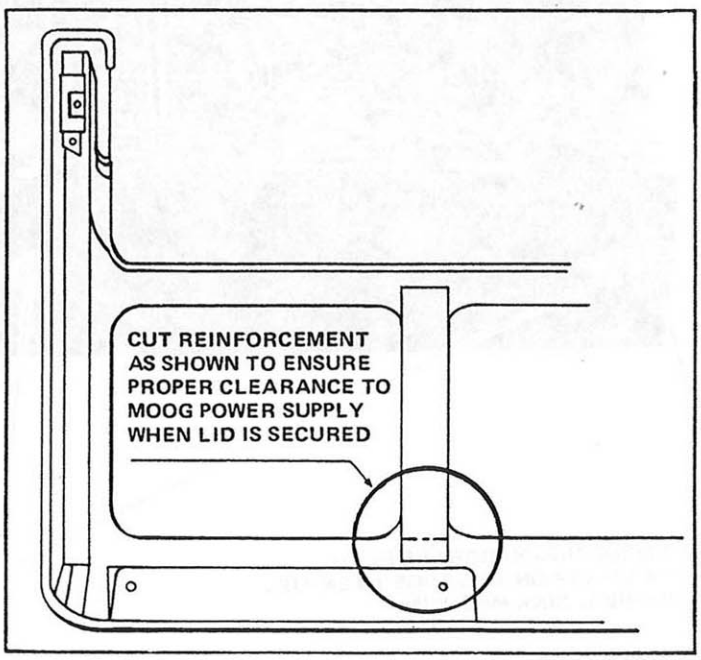


INSIDE VIEW TOP COVER

LOCATION: TOP LEFT BOARD 7. Refer to Figures 11 and 12.

REFERENCE OSCILLATOR

a. Prevent Jitter.

Change R57 and R83 from 10K ± 1% to 100K ± 5%.
Change C11 and C19 from 0.1uf polyester to 0.001uf polyester.

b. Prevent Oscillator Drift Due To Leaky Ribbon Controller.

Change R96 from selected value to 75K.
Add 10K resistor between CR1 anode and ground as shown (Figure 12).

c. Pitch Stability Due To Delicate Physical Construction Of Polycarbonate Capacitors.

Remove C13, C14, C21, C22 (0.001uf) polyester (white) or polycarbonate (green) capacitors.

Install new C13 and C21 (510pf) polystyrene capacitors as indicated.

d. Temperature Stabilization

Change R53, R55, R79, and R81 to 200K ± 1% resistors.
Cut two (2) traces on rear side of printed circuit board as shown in Figure 12.
Add a 953 ohm ± 1% resistor in two (2) places as shown in Figure 12.
Add a jumper wire in two (2) places as shown in Figure 12.

e. Reference Oscillator stability

Change R48 and R72 from 1K ± 1% to 10K ± 1%.
Change R97 from 40.2K ± 1% to 18.7K ± 1%.
Add a 0.01 disc capacitor (C40 and C41) across R49 and R75.

NOTE

Oscillators must be retuned after performing any of the above modifications. Allow settling time for polystyrene capacitors. (If possible, overnight burn-in.)

f. Phase Locked Loop Chirping. Figure 12.

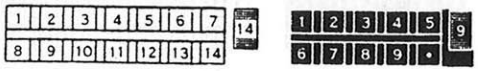
Cut trace between IC6 pin 13 and P73-6.
Cut trace between IC7 pin 13 and P73-9.
Tack on R197 and R198 4.7K ± 5% resistor in two (2) places as shown.

g. Improve Signal-To-Noise Ratio In Upper Two Octaves.

Add an 0.01 ceramic disc capacitor C42 between pins 1 and 2 of A28 (LM358 IC).

h. Prevent Shorting To Top Traces Of Circuit Board.

Raise one end of R94 and R95.



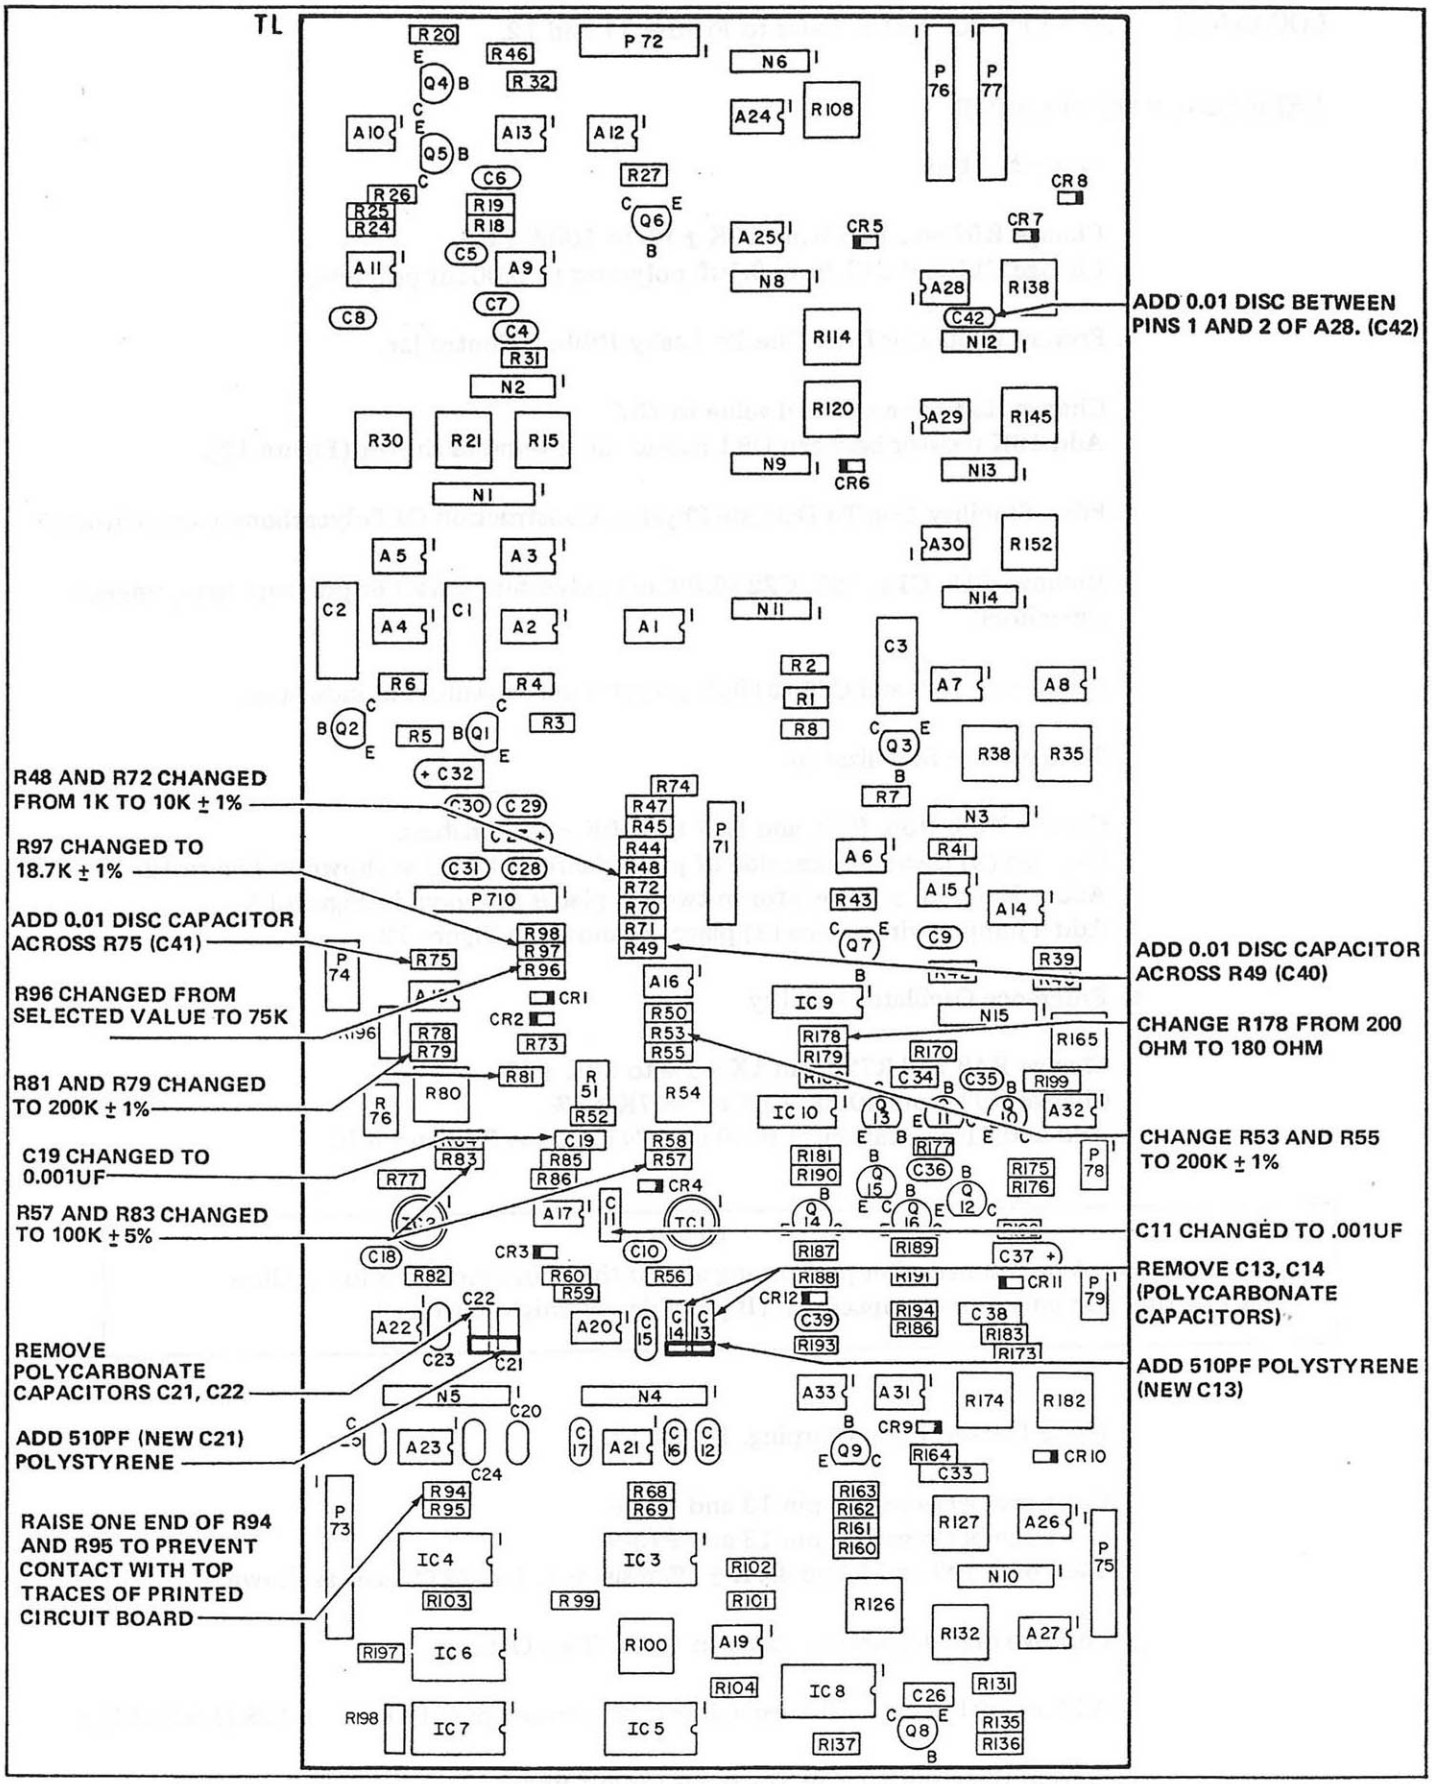


FIGURE 11 REFERENCE AND MODULATION WAVESHAPE AND KEYBOARD CONTROL PRINTED CIRCUIT TL BOARD 7 (POLYMOOG AND POLYMOOG KEYBOARD)

1207-12

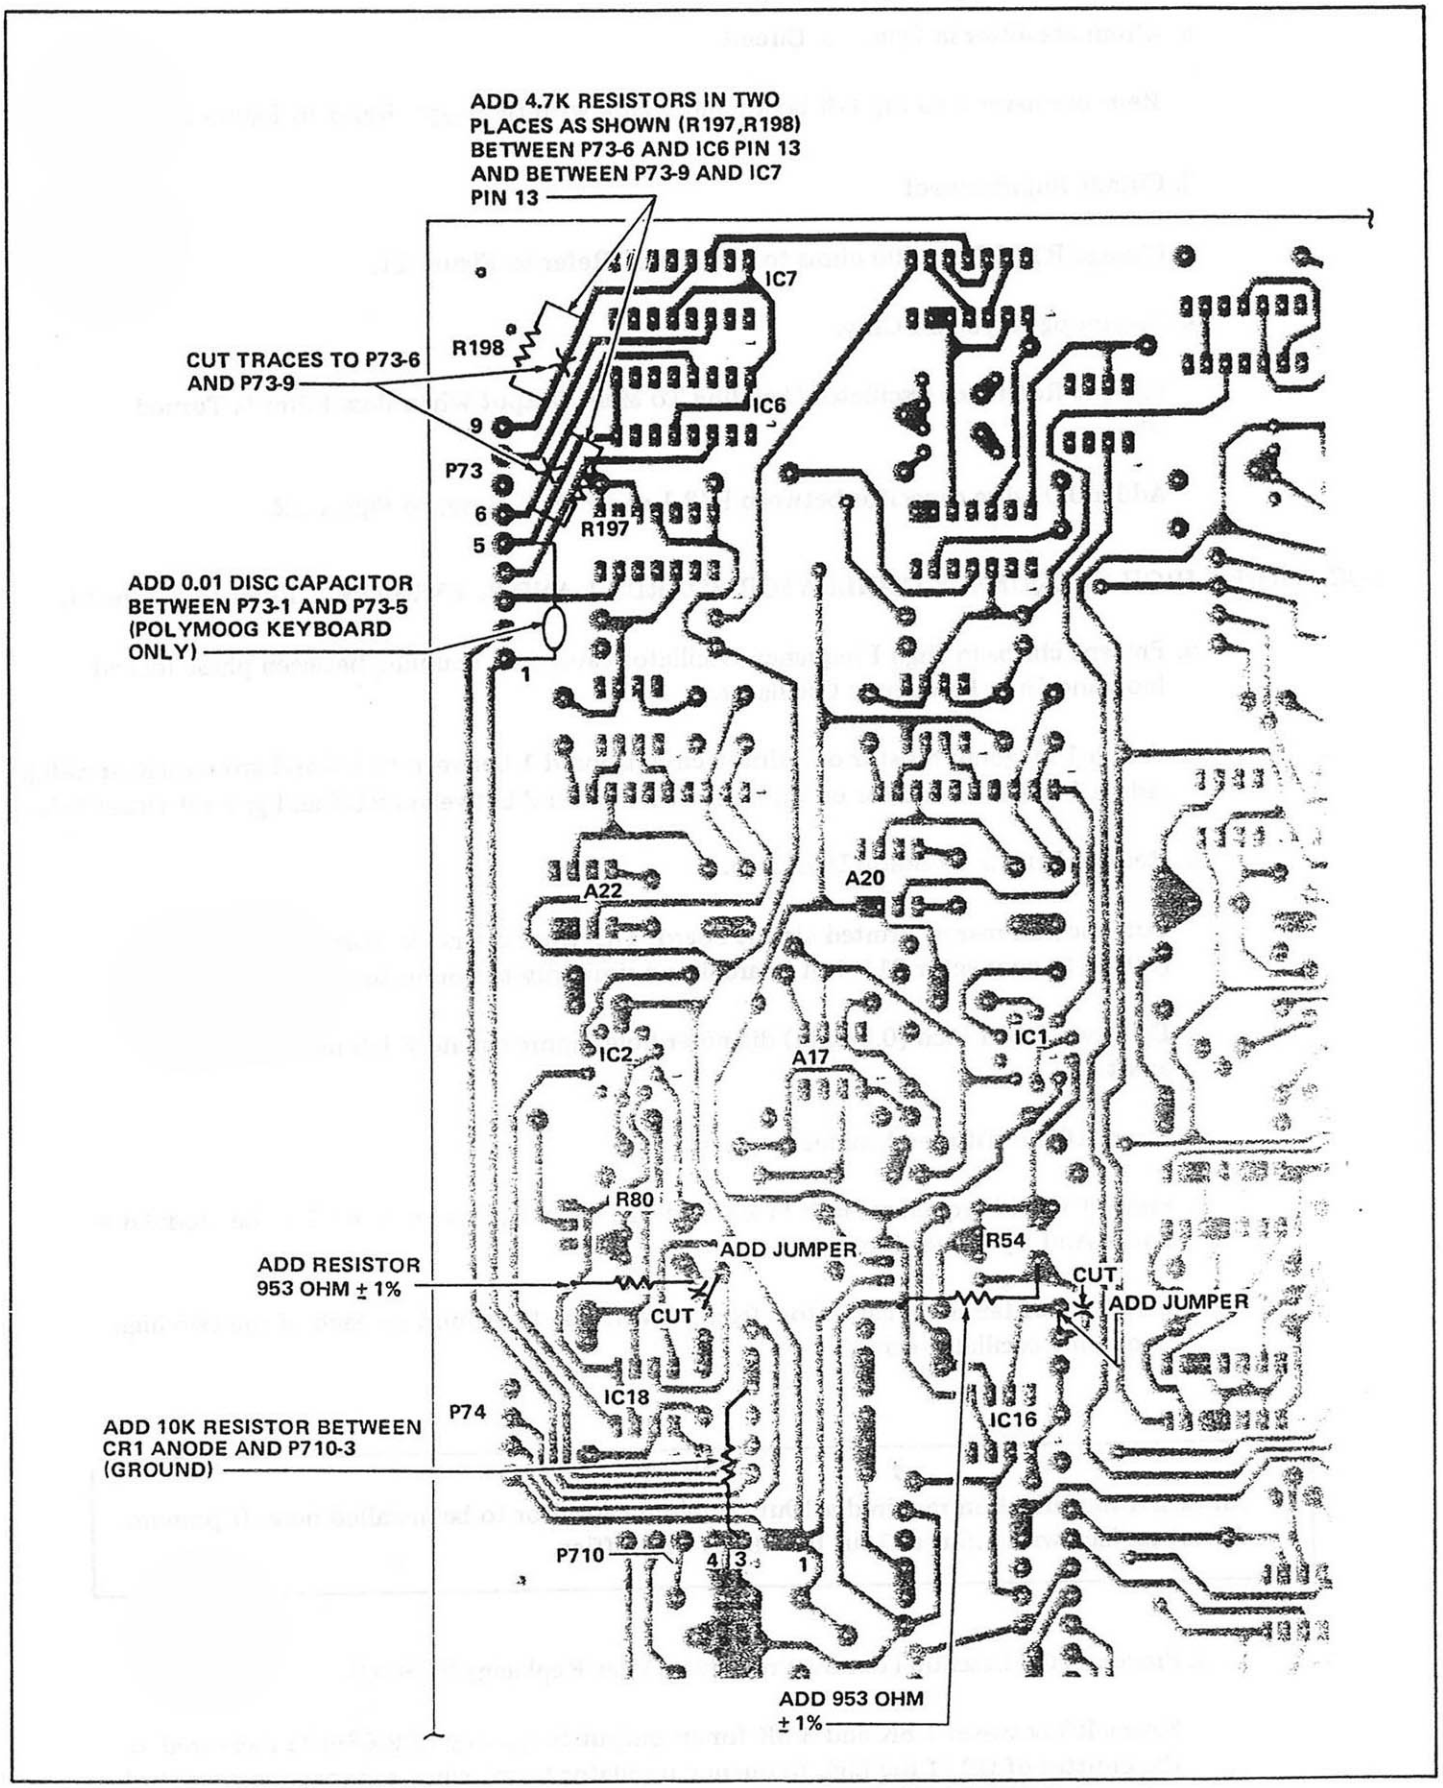

FIGURE 12 TEMPERATURE STABILIZATION CHANGES TL BOARD 7 (POLYMOOG AND POLYMOOG KEYBOARD)

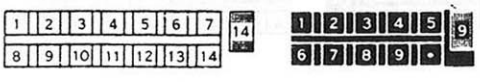


1207-13

LOCATION: TOP LEFT BOARD 7. (Continued)

i. Eliminate Jitter in Dynamic Circuit.

Re-route harness to top left board and secure with tie wraps. Refer to Figure 13.

j. Circuit Improvement.

Change R178 from 200 ohms to 180 ohms. Refer to Figure 11.

k. Polymoog Keyboard Only.

Prevent Reference Oscillator Coupling To Main Output When Bass Filter Is Turned On.

Add a 0.01 disc capacitor between P73-1 and P73-5. Refer to Figure 12.

LOCATION: HIGH FREQUENCY OSCILLATOR BOARDS 1 AND 2, VERSION 1. Refer to Figure 14.

a. Prevent chirps in High Frequency Oscillator caused by coupling between phase locked loop and High Frequency Oscillator.

Add a 1 megohm resistor on printed circuit board 1 between P11-5 and ground.(Rear Side).
Add a 1 megohm resistor on printed circuit board 2 between P21-5 and ground. (Rear Side).

b. Reduce Effects Of Static Discharge.

Cut trace on rear of printed circuit board. This trace connects from pin 4 of IC3 (4011) to connector P11-4 of board 1 and similarily to connector P21-4 of board 2.

Drill two 0.031 inch (0.69mm) diameter holes approximately 1/2 inch (12.7mm) apart.

Insert 10K resistor and solder in place.

c. Prevent High Frequency Hash From Appearing On The Clock Lines To The Modulator Cards And Dynamics Circuit.

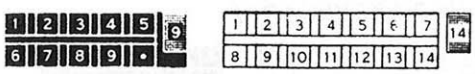
Install 1.5uf tantalum capacitors from +5 volt line to ground on each of the two high frequency oscillator cards.

NOTE

An earlier modification required a 10uf tantalum capacitor to be installed here. If present, do not replace with 1.5uf as 10uf tantalums will suffice.

d. Prevent TOS Latchup (Follow Procedure After Replacing TOS IC).

Select R3 between 1.8K and 3.3K for an output frequency of 2.66mHz measured at the emitter of Q2 of the high frequency oscillator board when external pitch control volume input ≥ 3 VDC.



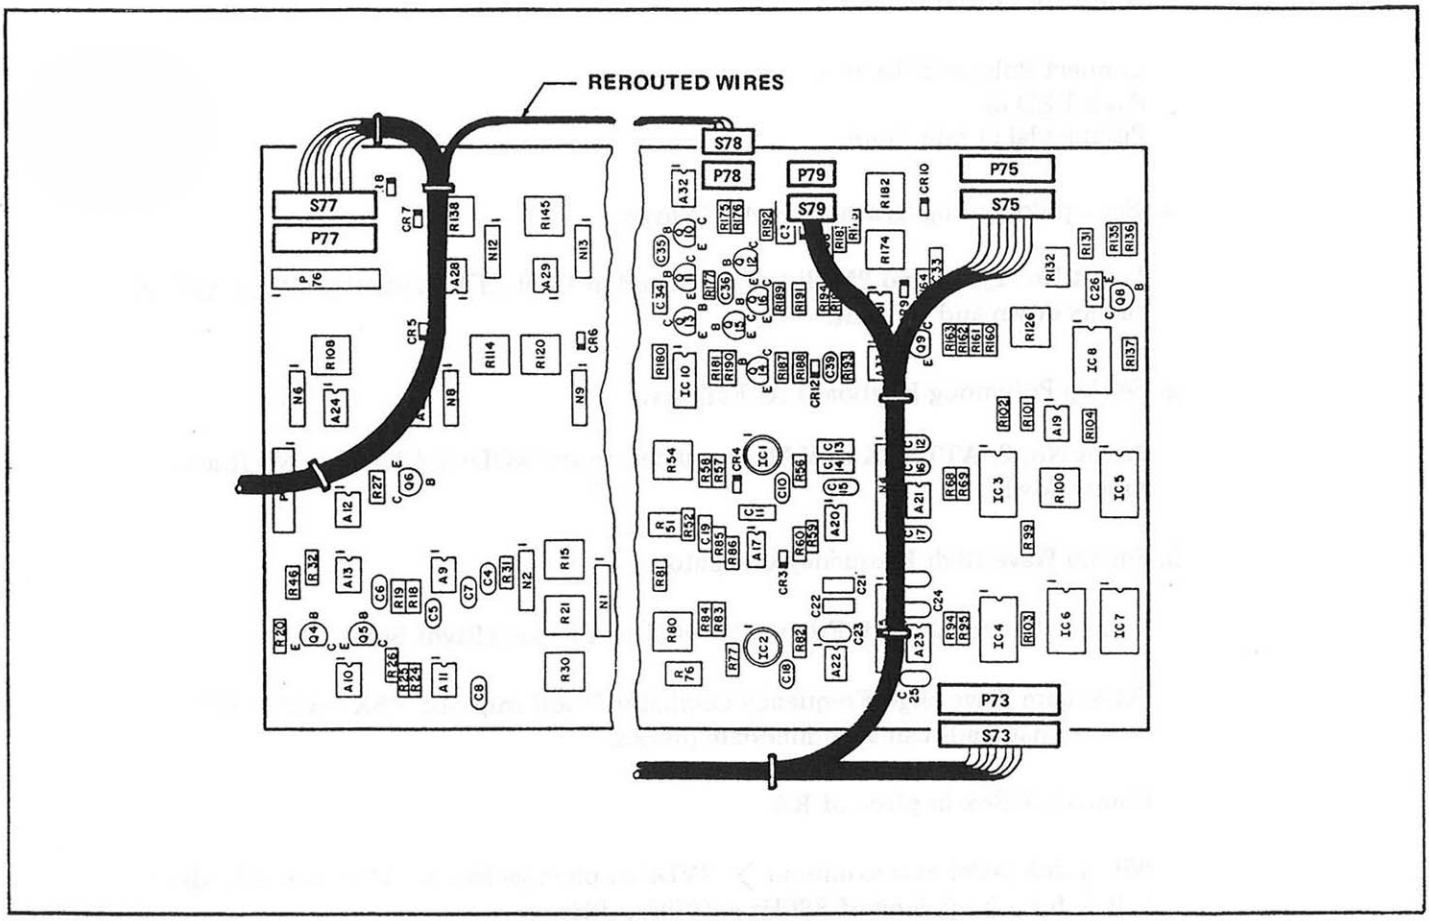


FIGURE 13 TL BOARD HARNESS REROUTING (POLYMOOG AND POLYMOOG KEYBOARD)

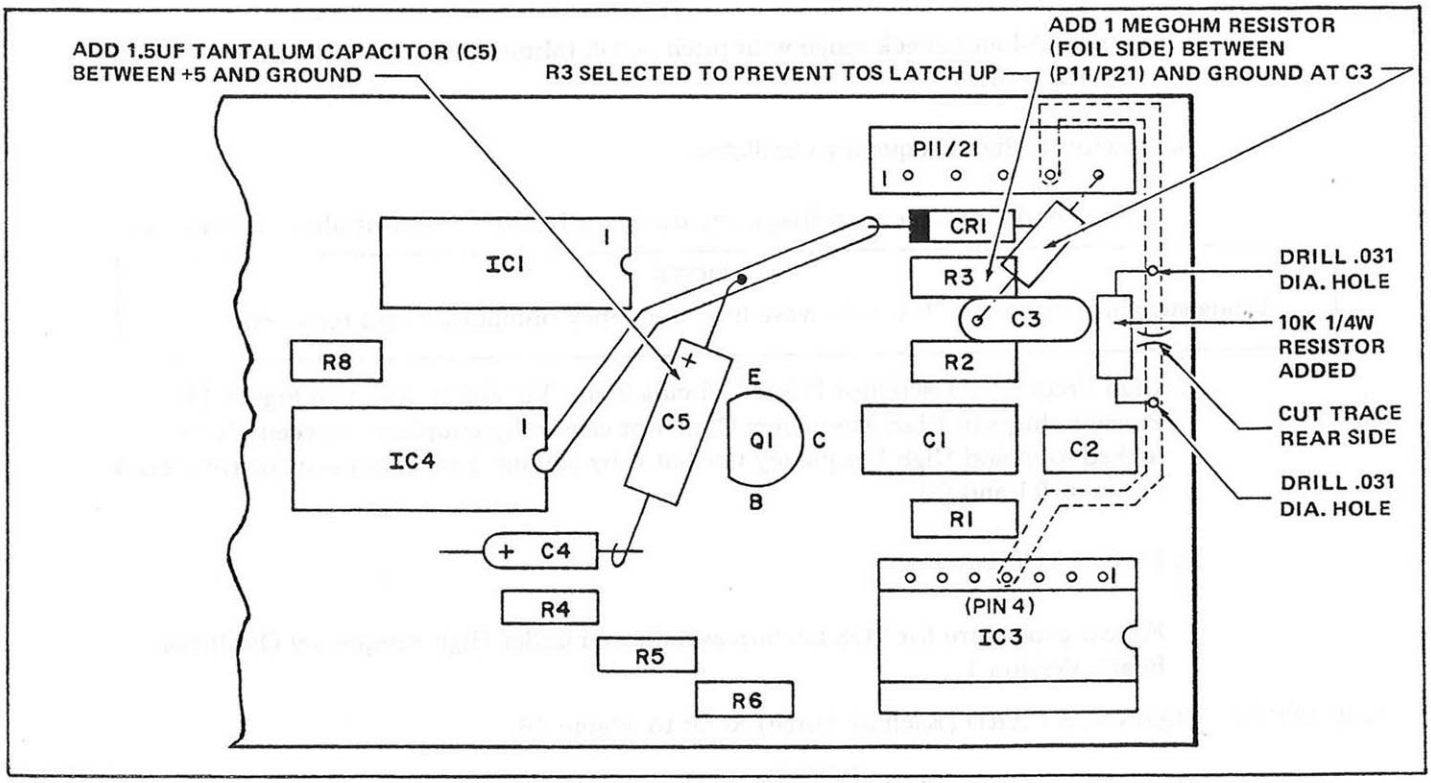

FIGURE 14 HIGH FREQUENCY OSCILLATOR PRINTED CIRCUIT HFO BOARD (VERSION 1) (POLYMOOG AND POLYMOOG KEYBOARD)

1207-15

e. Alternate Procedure Setup.

Connect Polypedal to unit.
Pitch LED on.
Pitch pedal at minimum.

f. Set Up Polymoog Synthesizer As Follows:

Preset No. 1, FM and PM sliders down and in VAR; ⎍ SHAPE/MODULATION sliders down and in VAR.

g. Set Up Polymoog Keyboard As Follows:

Preset No. 2, ATTACK in VAR and slider down; MODULATION in VAR and sliders down.

h. Square Wave High Frequency Oscillator.

Remove Sawtooth High Frequency Oscillator Board (Right Side).

On Square Wave High Frequency Oscillator Board snip out 1.5K resistor R3. Ensure that leads can accommodate probes.

Connect R Box in place of R3.

With pitch pedal at maximum (> 3VDC at pitch jack) and A4 depressed, adjust R Box for a frequency of 880Hz + 100Hz, -0Hz.

Insert selected value resistor and solder in place.

Depress A4 and check range with pitch pedal. (Minimum 440Hz) (Maximum 880Hz, +100Hz, - 0Hz).

i. Sawtooth High Frequency Oscillator.

Remove square wave high frequency oscillator board and repeat above procedure.

NOTE

A long sustain is normal with square wave high frequency oscillator board removed.

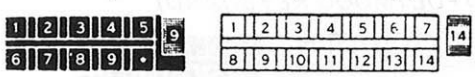
j. High Frequency Oscillator Printed Circuit Board Version 2. Refer to Figure 15. Prevent chirps in High Frequency Oscillator caused by coupling between phase locked loop and High Frequency Oscillator by adding 1 megohm resistor (rear side) between R1 and C3.

k. Prevent TOS Latchup.

Follow procedure for TOS latchup as indicated under High Frequency Oscillator Board Version 1.

LOCATION: BALANCE CARD (Each of Three) Refer to Figure 16.

Reduce parasitic oscillation by adding a 500pf ceramic disc capacitor between pins 1 and 2 (V+ and V- respectively) on each of the three (3) balance cards.



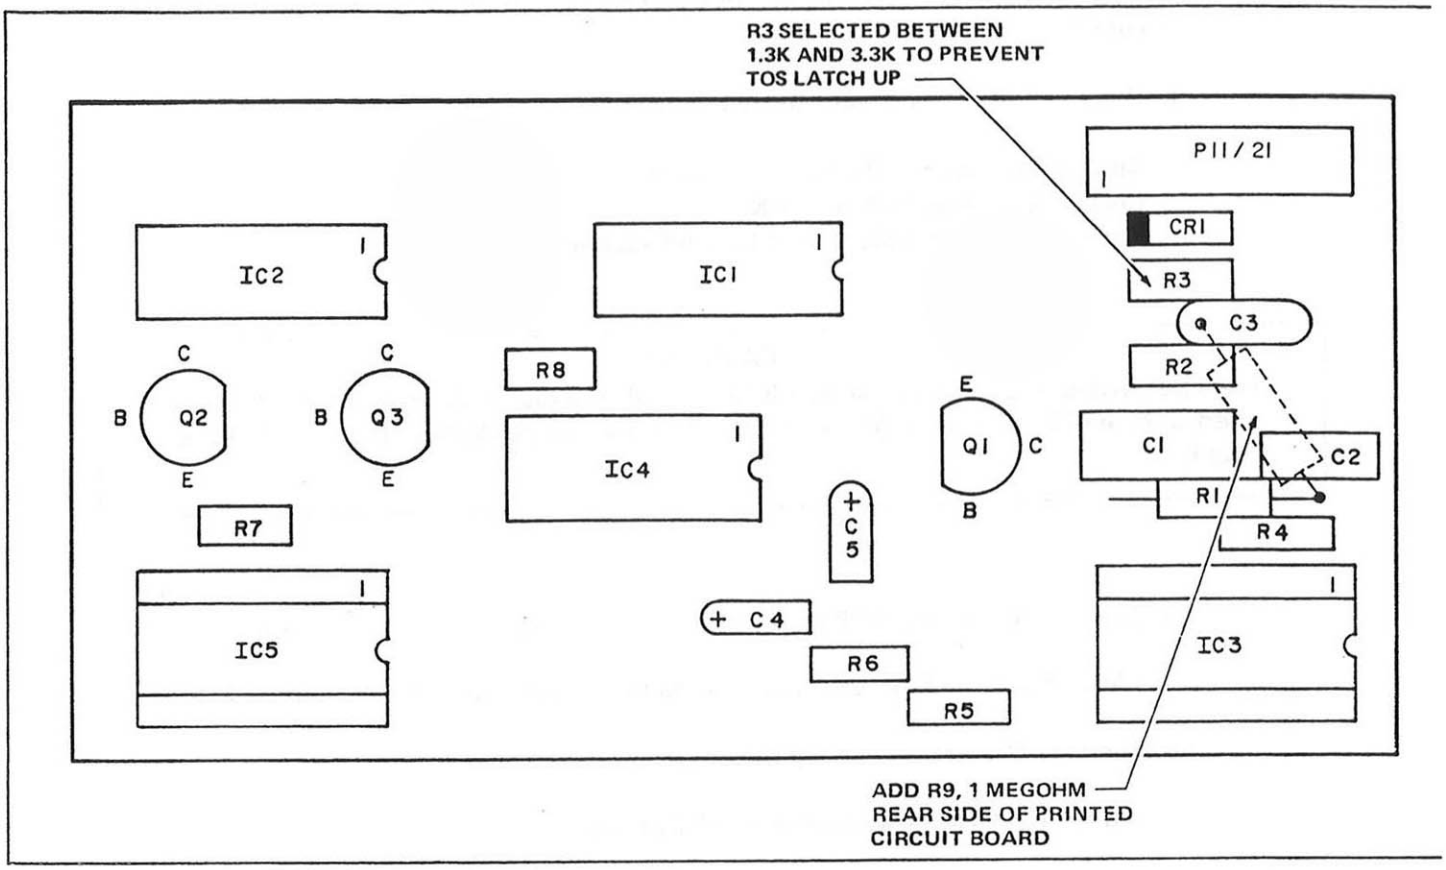


FIGURE 15 HIGH FREQUENCY OSCILLATOR PRINTED CIRCUIT HFO BOARD (VERSION 2) (POLYMOOG AND POLYMOOG KEYBOARD)

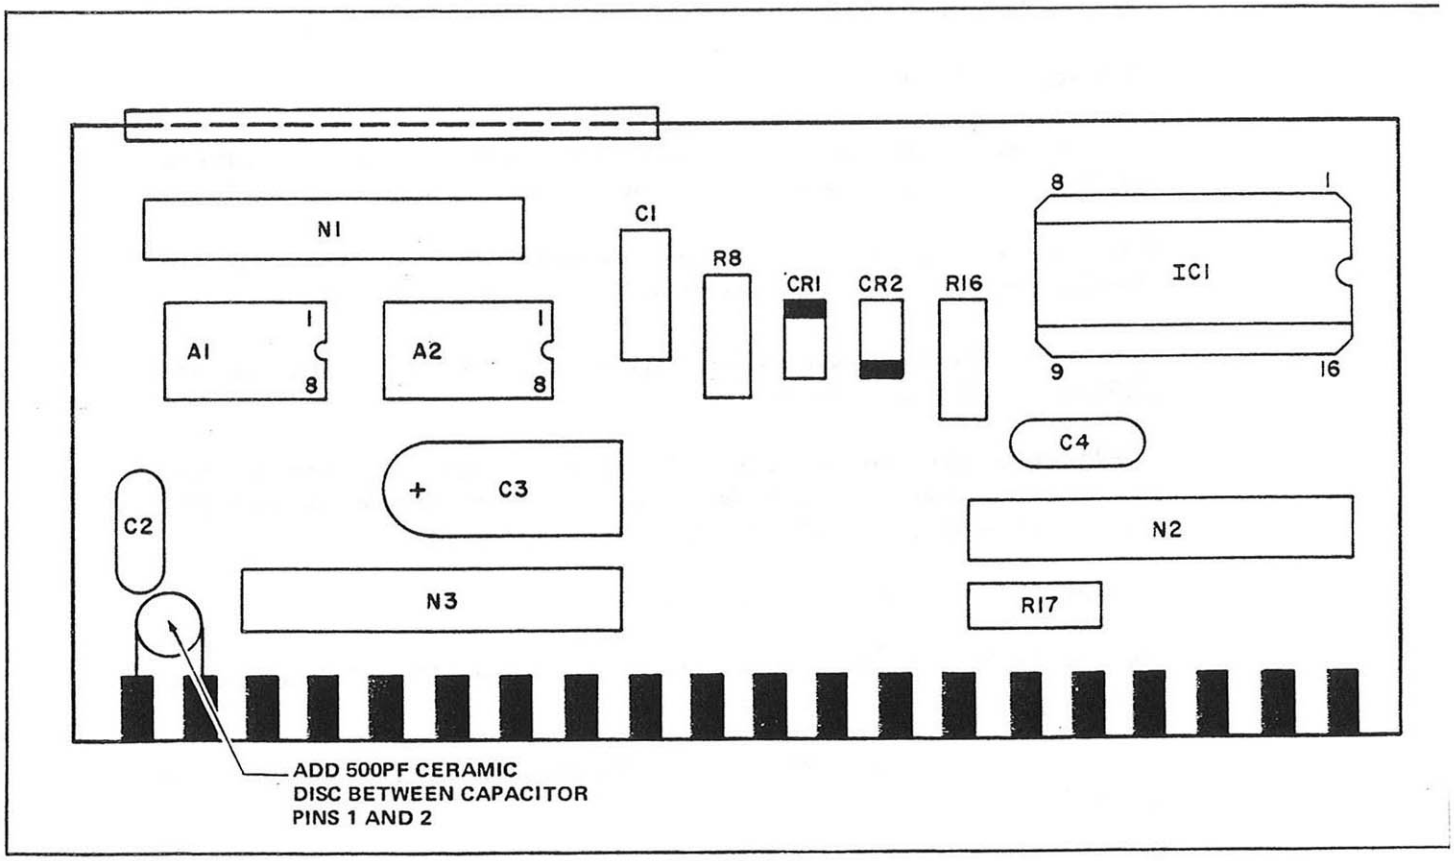

FIGURE 16 BALANCE CARD (POLYMOOG AND POLYMOOG KEYBOARD)

1207-17

LOCATION: TOP RIGHT PRINTED CIRCUIT BOARD 9 (VCF and Keyboard Circuit) Refer to Figure 17.

a. Contour Generator Temperature Stability.

Change R68 from 470K to 4.7 megohm.
Change R71 from 15K to 160K.
Change R70 from 10K cermet to 200K carbon trim.

CAUTION

Exercise extreme care when removing R70 trimpot. If a plated through hole is damaged, insert a piece of buss wire in the damaged hole and solder in place on both sides of the board.

b. Eliminate Click Caused With Attack And Decay Sliders Set At Minimum.

Add R183, 100 ohm resistor in series between pin 8 and +15V supply at IC5.

c. Eliminate Oscillation In Brightness Circuit.

Add R187, 2.7K between pins 1 and 4 of A3.

d. Reduction Of Drift In Keyboard Sample And Hold Circuit.

Change C25 from 0.1 to 0.47 polyester.

e. VCF Noise Reduction.

Remove small shield board located beneath the VCF board and replace with large shield. Ensure that foil side faces the modulator cards to prevent short circuits.

Install ground strap and locate one end between new shield and metal standoff. Install other end to front panel subassembly as shown in Figure 24.

Change printed circuit board mounting screw securing shield, etc., from 3/8 inch (9.5mm) to 1/2 inch (12.7mm).

Level printed circuit board by adding 6-32 nuts as shims between top of mother board and the two center standoffs as indicated. Secure hardware in place. This prevents stress buildup at N6 which causes VCF shutdown.

f. Prevent Clicks In Output From S-TRIG.

Reroute S-Trig (orange) wire directly between P91-4 and P1-2 (S-TRIG output connector on rear panel) as follows:

Trace orange wire between P91-4 and P02-2 and cut at P02-2 end. Only solid orange wire in P02 connector.

Pull orange wire out of harness and strip end.

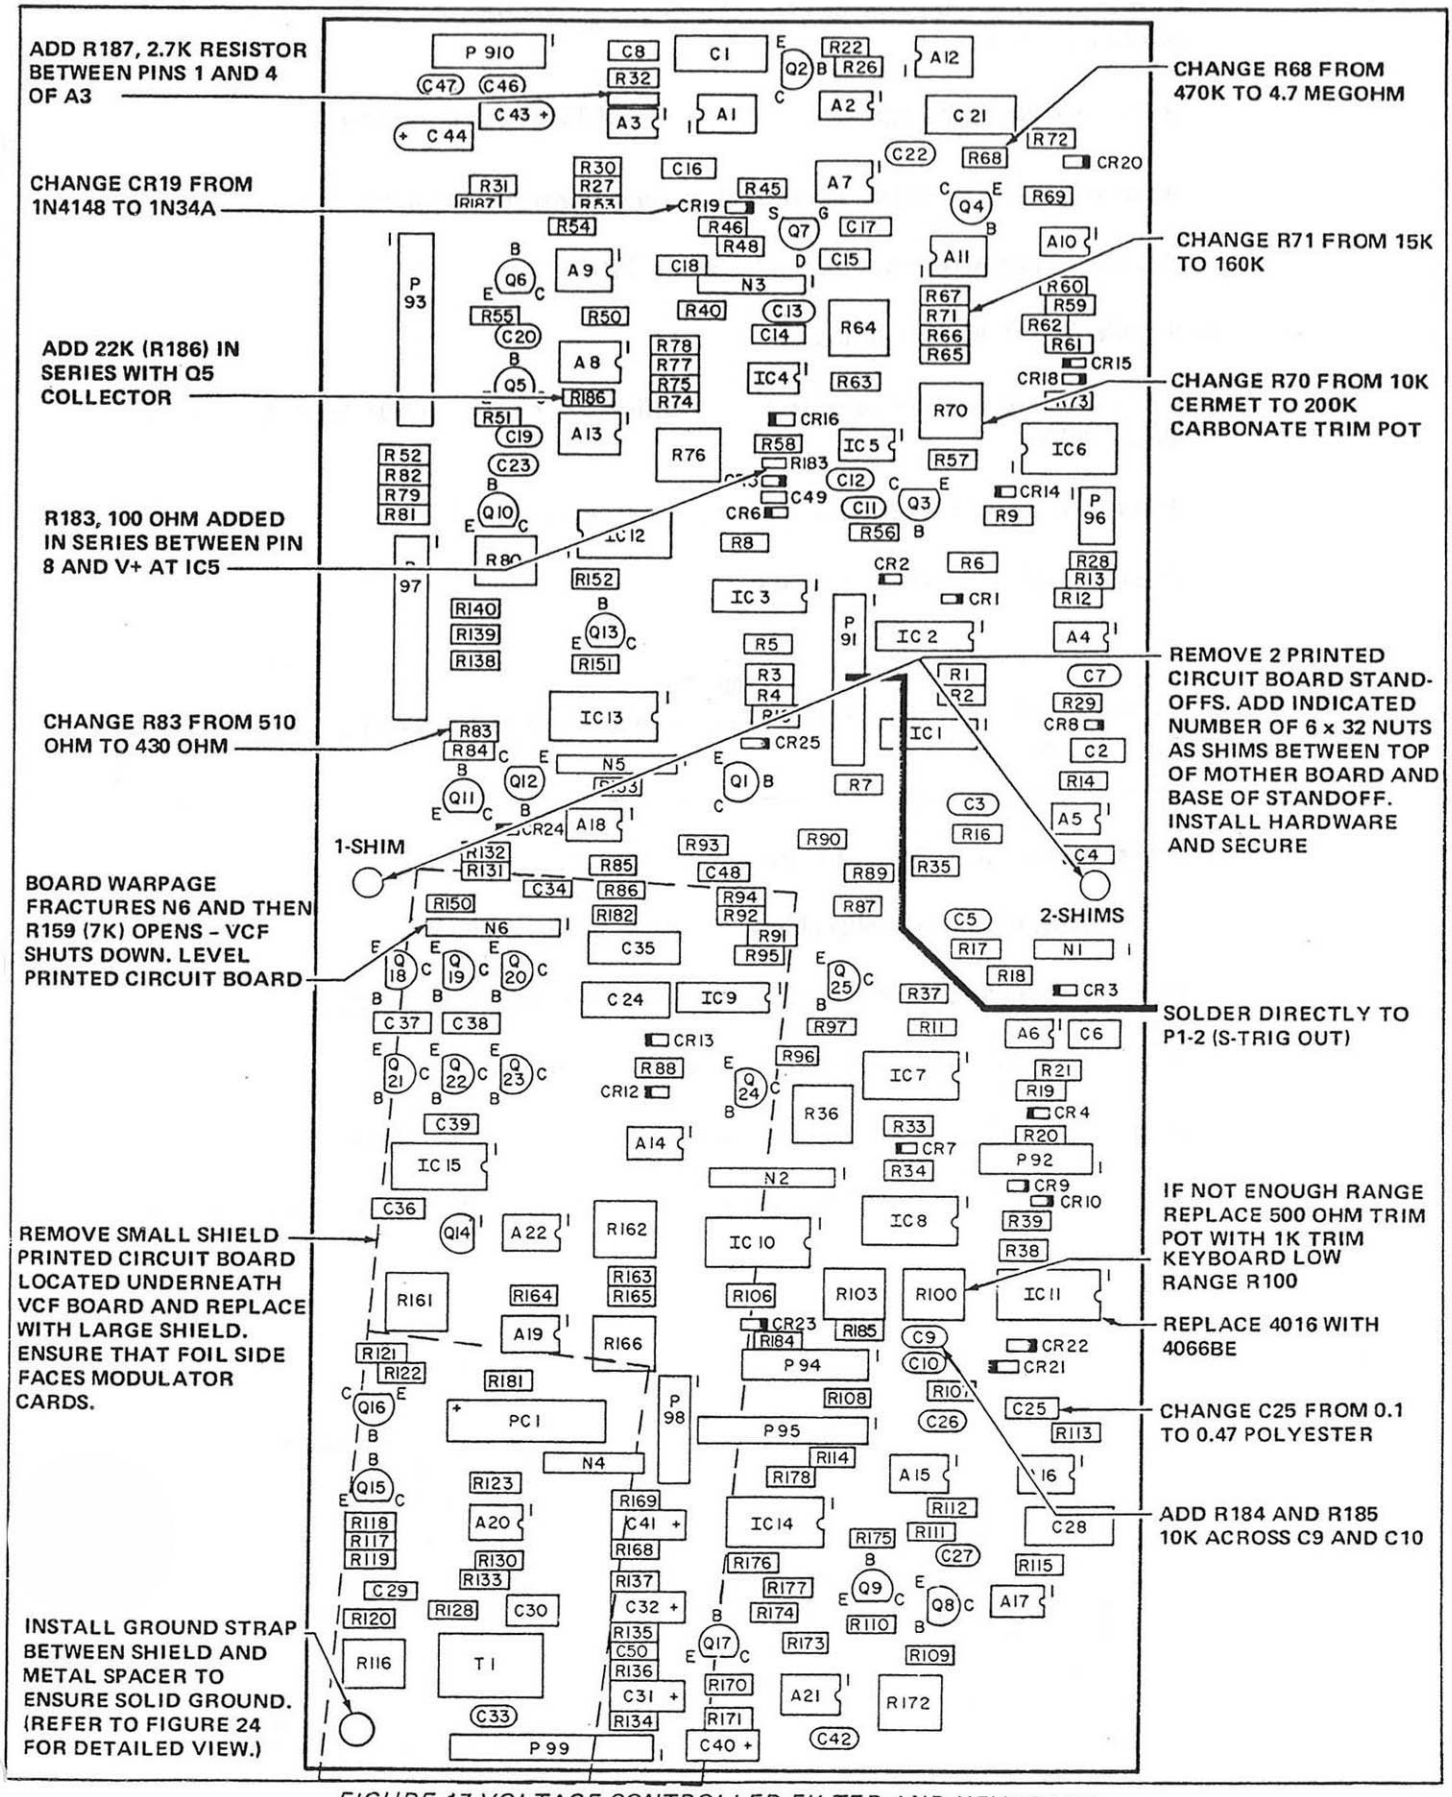

FIGURE 17 VOLTAGE CONTROLLED FILTER AND KEYBOARD CIRCUIT PRINTED CIRCUIT TR BOARD 9 (POLYMOOG)

Unsolder orange wire attached to S-TRIG out connector P1-2 and cut as short as possible to harness.

Attach and solder orange wire from P91-4 to S-TRIG out connector P1-2.

g. Improve Linearity Of The External Keyboard Control Voltage Output.

Replace IC11 (4016) with an RCA CD 4066 BE.

h. Sample And Hold Q5 Failure.

If circuit is not working prior to this modification, change BOTH A8 (CA3080) and Q5 (2N3906).

Add a 22K resistor R186 in series with the collector of Q5.

Change CR19 1N4148 from 1N34A.

NOTE

The above change is in conjunction with the change in the right hand control board as specified in step i below.

i. Right Hand Control Board 11. Refer to Figure 22.

In modulation network (N2) change R5 from 200K to 100K.

j. Improve Triggering When Operating the VCF In The High/Low Split Mode.

Add 10K resistor across C9 and C10. Refer to Figure 18.

k. Decrease Scale Factor Of VCF to Conform With Latest Specifications.

Change R83 from 510 ohm to 430 ohm. VCF must be calibrated after this change.

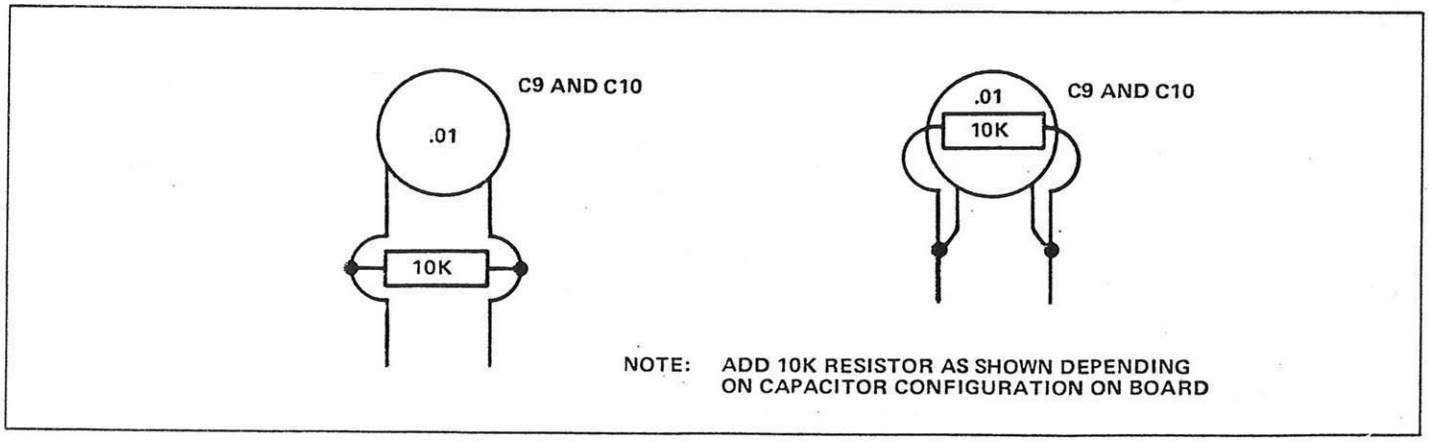

FIGURE 18 TOP RIGHT BOARD 9 RESISTOR ADDITION (POLYMOOG)

LOCATION: TOP CENTER PRINTED CIRCUIT BOARD 8. Refer to Figure 19.

a. Prevent Clicks and Pops in Resonators.

Cut trace between S82 pin 5 and R10 on the component side of the printed circuit board.

Tack on and solder a 1.0uf polyester axial lead capacitor in series with P82-5.

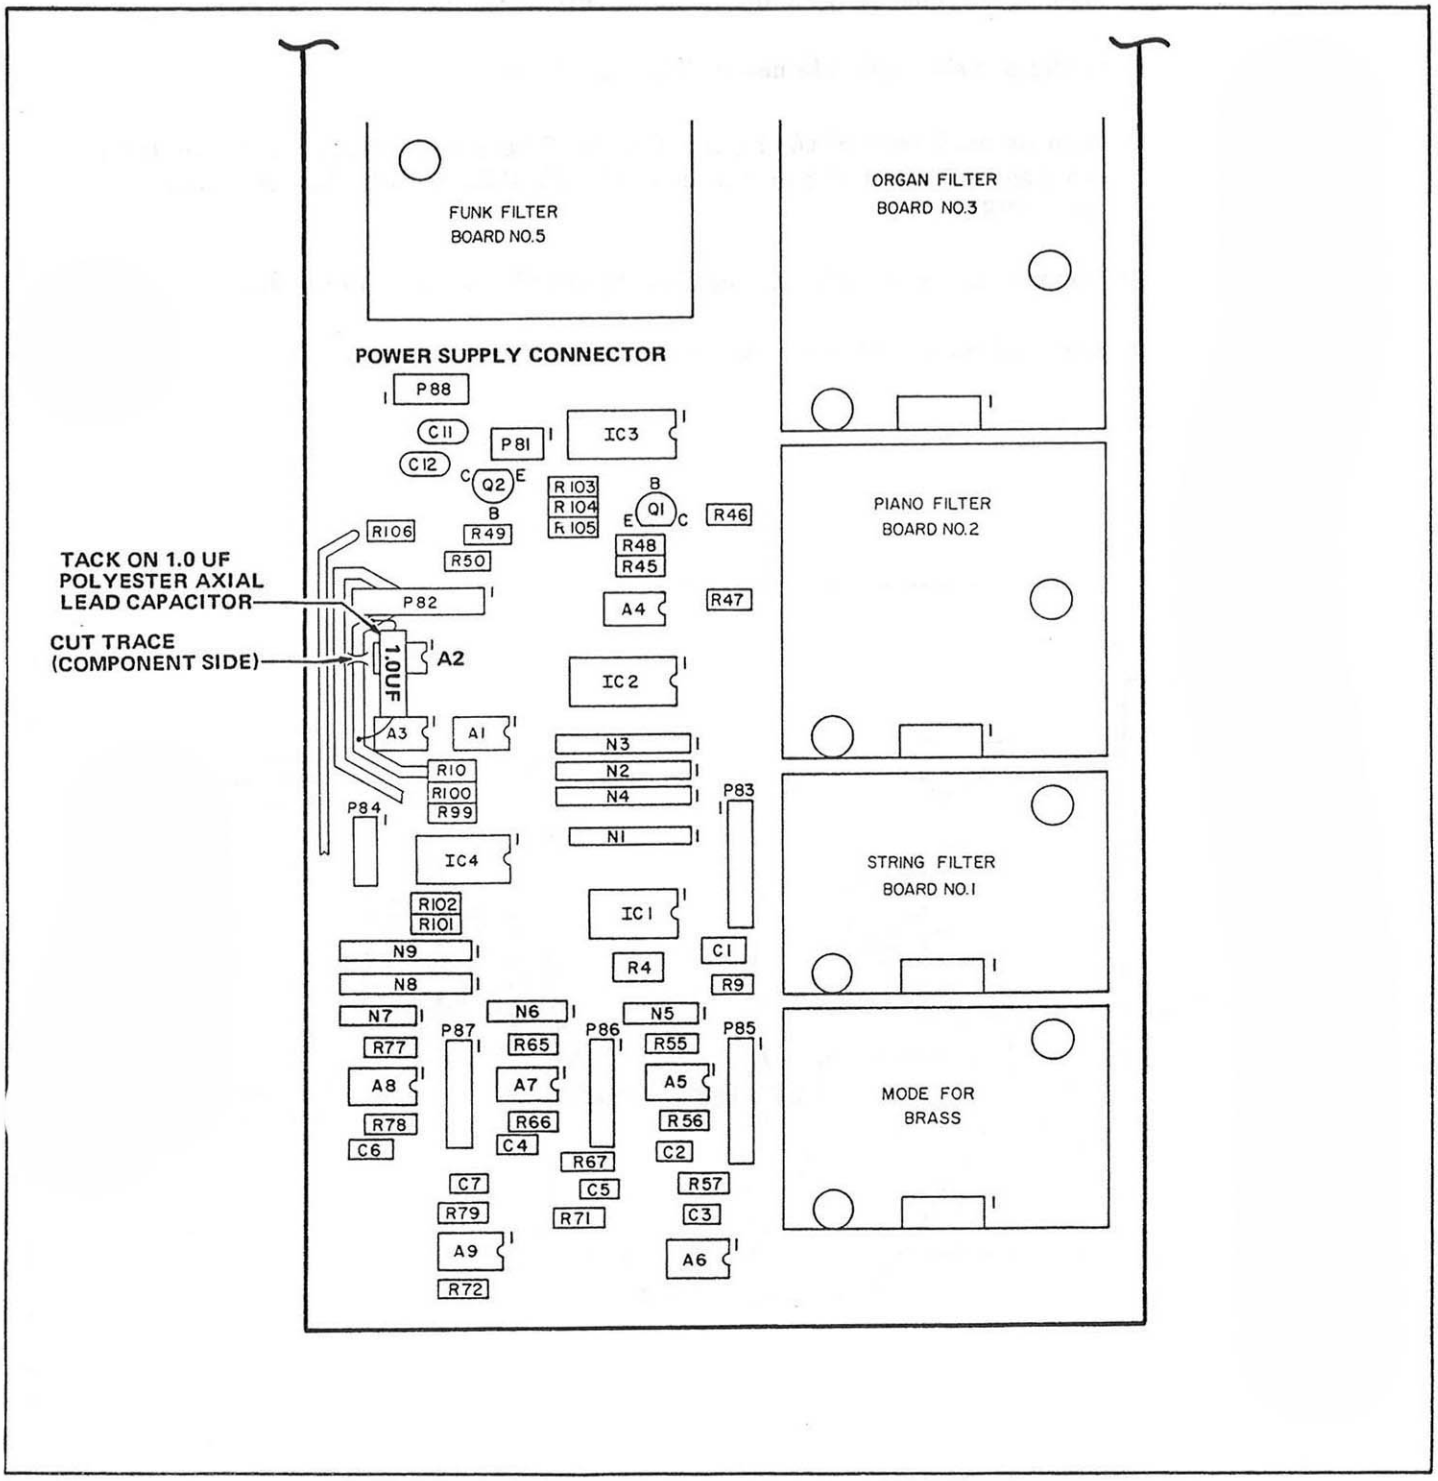

FIGURE 19 FIXED AND VARIABLE RESONANT FILTERS
PRINTED CIRCUIT TC BOARD 8 (POLYMOOG)

NOISE REDUCTION

LOCATION: TOP CENTER AND TOP RIGHT BOARDS. Refer to Figure 20.

To determine if this change is needed, connect a piece of buss wire between the 4.85 VDC rails of each board as designated. Listen to instrument with all MIX sliders down and if noise is significantly reduced, proceed as follows:

a. Drill .040 inch diameter hole on top center board as shown. Remove solder mask approximately 5/32-inch diameter around hole.

b. Solder in a single pin CIS header (P89) into hole.

c. Remove pin 2 from S910 (Figure 20 on VCF board). Strip back insulation from pin 2 and solder on an 8-inch piece of No. 22 AWG white/yellow wire with a single CIS socket.

d. Connect wire and socket to single pin CIS (S89) on top center board.

e. Use twist lock to anchor wire to existing harness on top center board.

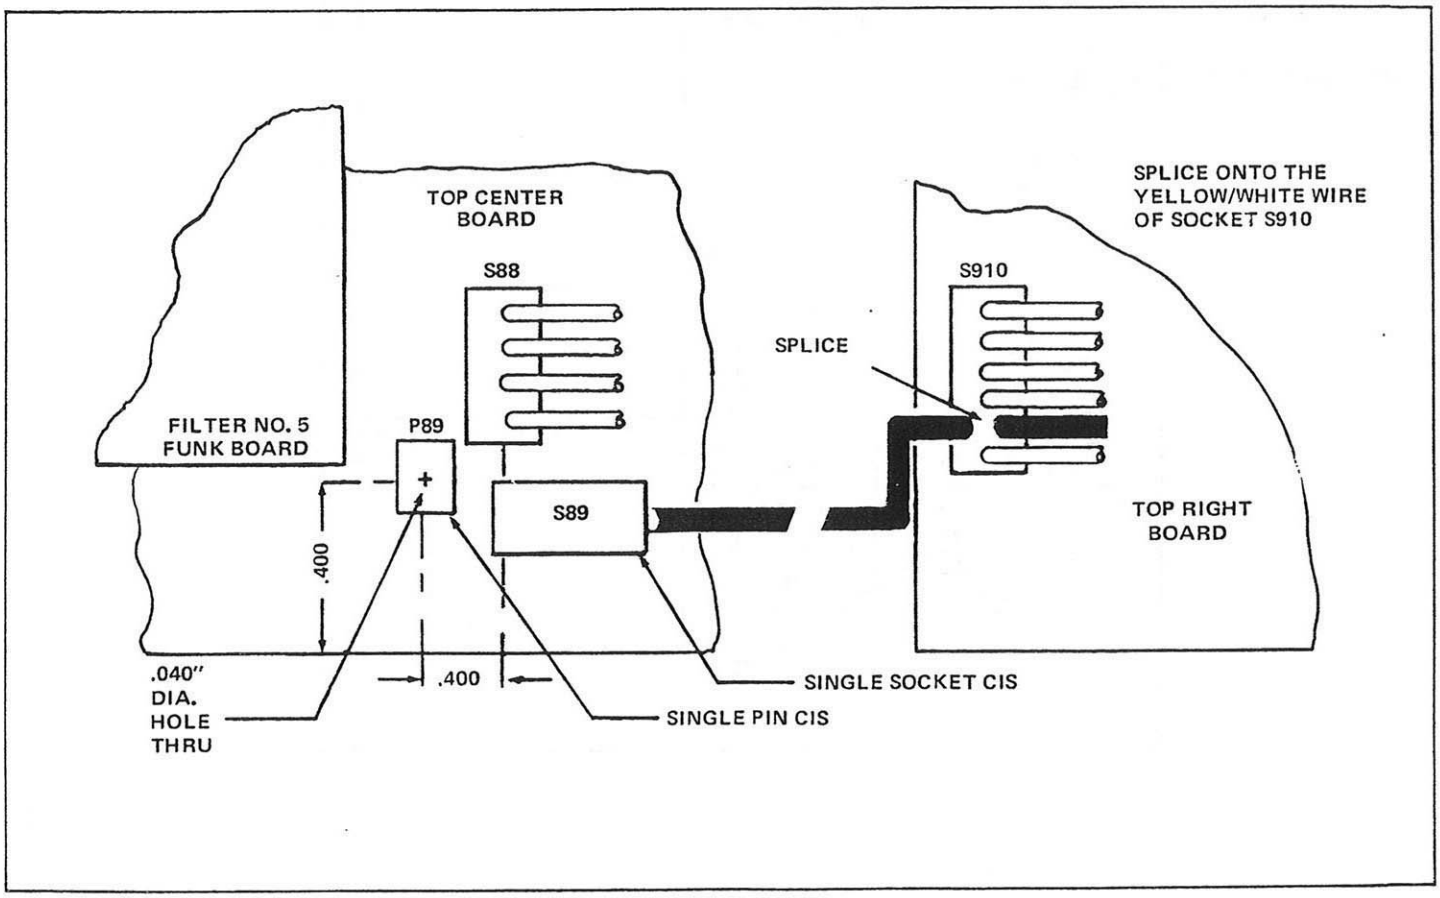

FIGURE 20 NEW CONNECTOR BETWEEN BOARDS (POLYMOOG)

LOCATION: LEFT HAND CONTROL BOARD 10. Refer to Figure 21.

a. Rank Tune Modification For Improved Oscillator Stability.

Change R17 from 510K or 430K to 422K ± 1%.
Change R18 from 1 megohm to 820K.
Change CR81 from 1N34A to 1N4148.

b. Pulse Width Modification For Improved Uniformity At 5% Setting.

Add a 300K resistor on bottom of board in three places:

Between pins 2 and 5 of IC15.
Between pins 11 and 14 of IC19.
Between pins 11 and 14 of IC17.

LOCATION: RIGHT HAND CONTROL BOARD 11. Refer to Figure 22.

a. Reduce Effects of Static Discharge. Refer to Figure 23.

Remove mounting hardware for the front panel assembly and fold back the assembly to expose the underside of the control boards.

Remove the four Phillips screws securing the front of the control board and discard all washers.

Obtain four (4) serrated ground lugs and cut to required length.

Reinstall original mounting screws and solder lugs to ground points.

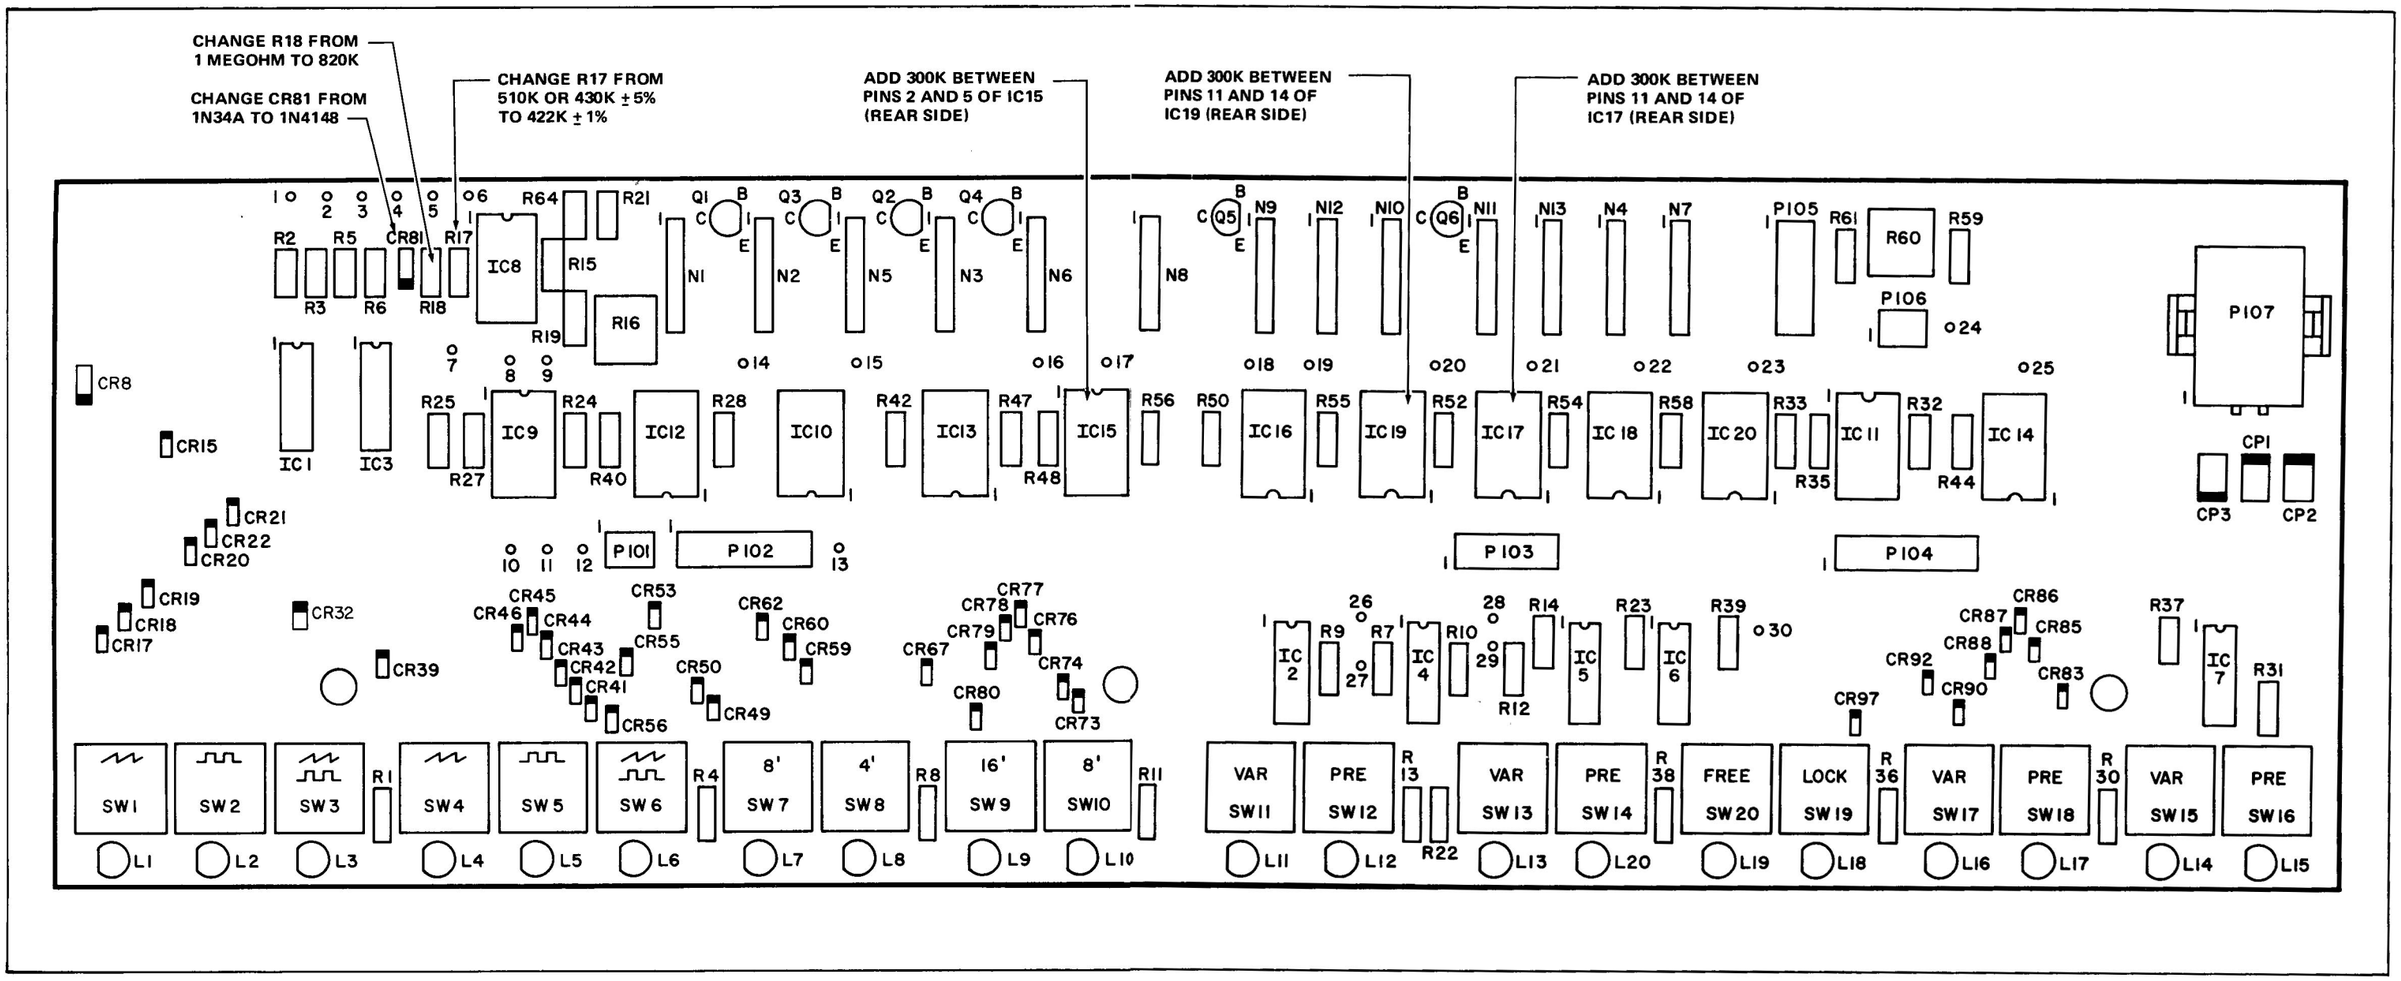

FIGURE 21 LEFT HAND CONTROL PRINTED CIRCUIT CL BOARD 10 (POLYMOOG)

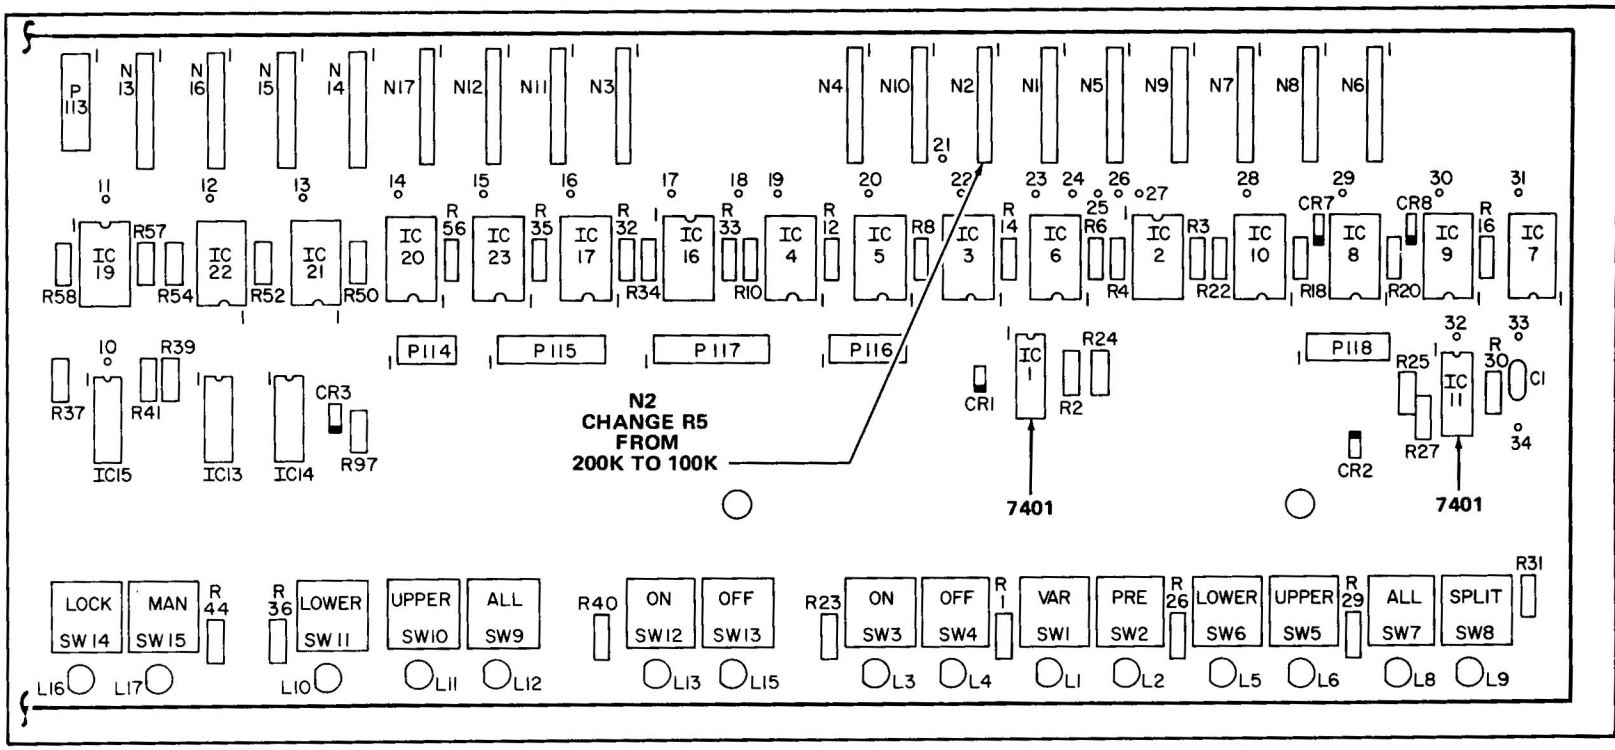

FIGURE 22 RIGHT HAND CONTROL AND MASTER PRESET PRINTED CIRCUIT CR BOARD 11 (POLYMOOG)

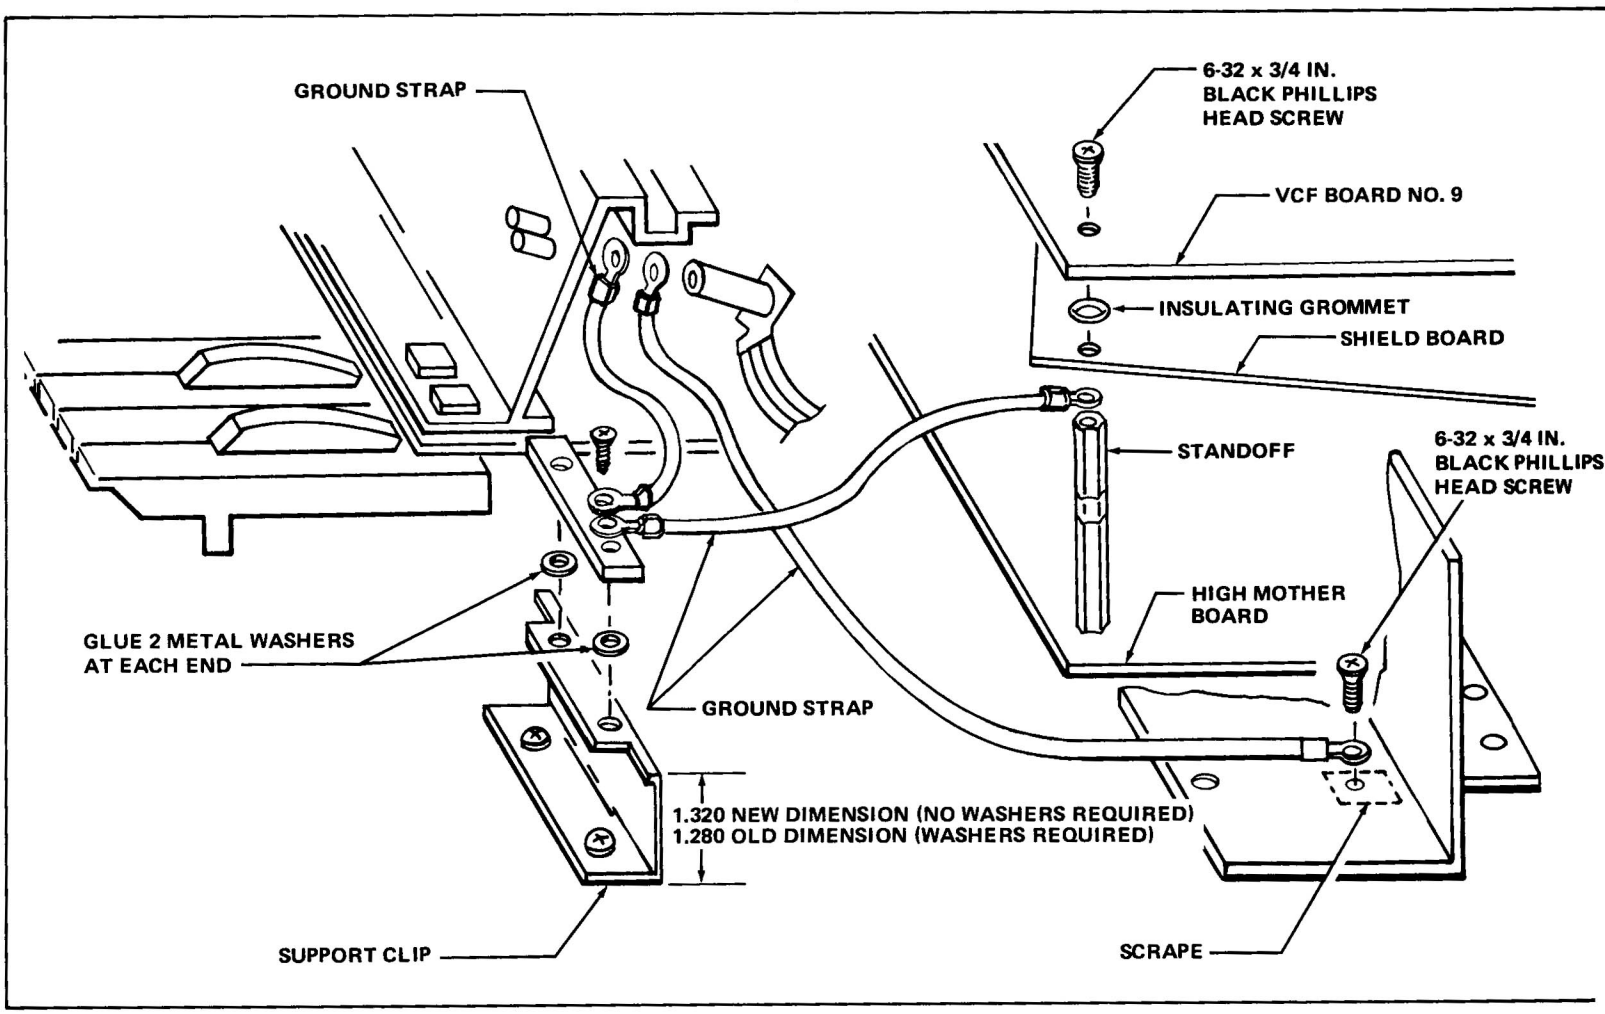

FIGURE 24 GROUND STRAP INSTALLATION (POLYMOOG)

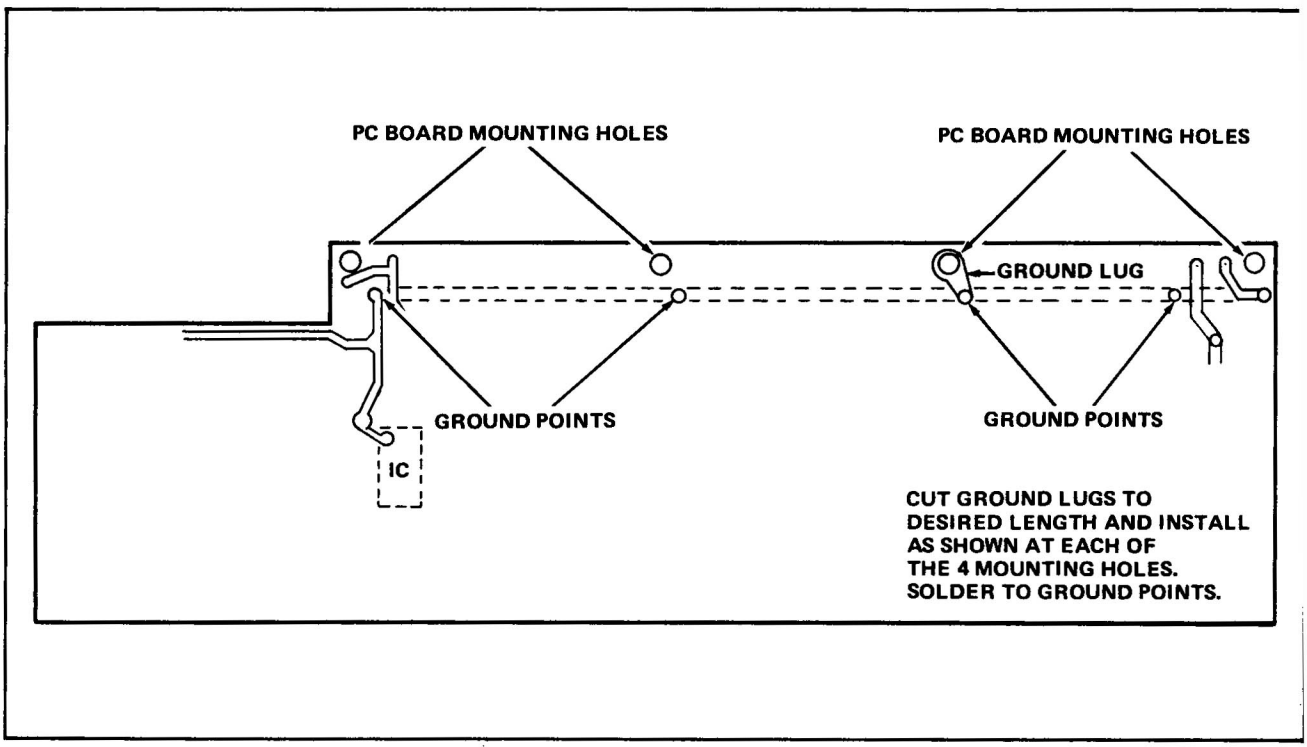

FIGURE 23 RIGHT HAND CONTROL BOARD - BOTTOM VIEW (POLYMOOG)

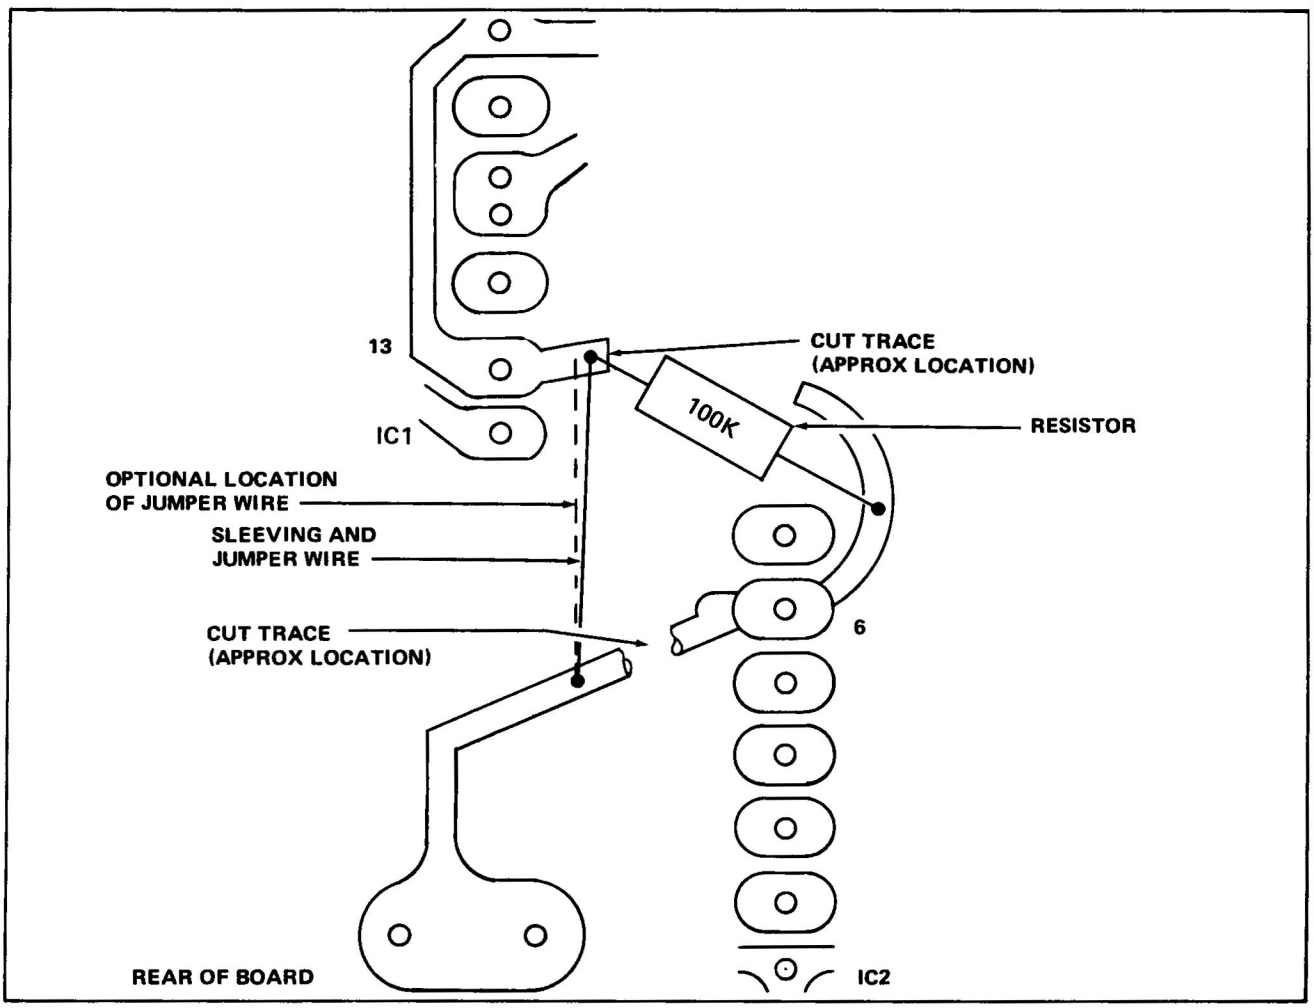

FIGURE 25 RIGHT HAND CONTROL (POLYMOOG)

LOCATION: RIGHT HAND CONTROL BOARD 11. (Continued)

b. Install One Foot Ground Strap With Ground Lugs At Each End. Refer to Figure 24.

Connect one end to the front panel assembly as shown on the right side of the unit.

Remove one of the mounting screws securing the rear panel extrusion to the base of the instrument at the right corner. With emery cloth or appropriate abrasive material, remove the anodizing on the aluminum in the area of the mounting screw to expose the metal. Connect other end to this point and securely tighten the mounting screw. This establishes a "solid" ground to the front panel assembly.

c. Sample And Hold Circuit Reliability Modification. Refer to Figure 25.

Cut the following traces on the back of the board:

Between IC1 pin 13 and IC2 pin 6.
Between IC2 pin 6 and pin 25 of SVVP output.

Attach 100K resistor between IC1 pin 13 and IC2 pin 6.

Add jumper wire from IC1 pin 13 to SWP output (pin 25) with 3/4-inch sleeving.

d. In Conjunction with Sample and Hold Q5 Failure as Described on VCF Board 9 Procedure:

In modulation network (N2) change R5 from 200K to 100K. Refer to Figure 22.

LOCATION: REAR PANEL MODIFICATION FOR SIMULTANEOUS MIX OUTPUTS FROM XLR CONNECTOR AND PHONE JACK. Refer to Figure 26.

a. Remove jumper from XLR BAL MIX output connector S2-2 to MIX jack J10-1 and add a green jumper from S2-1 to J10-3 (ground).

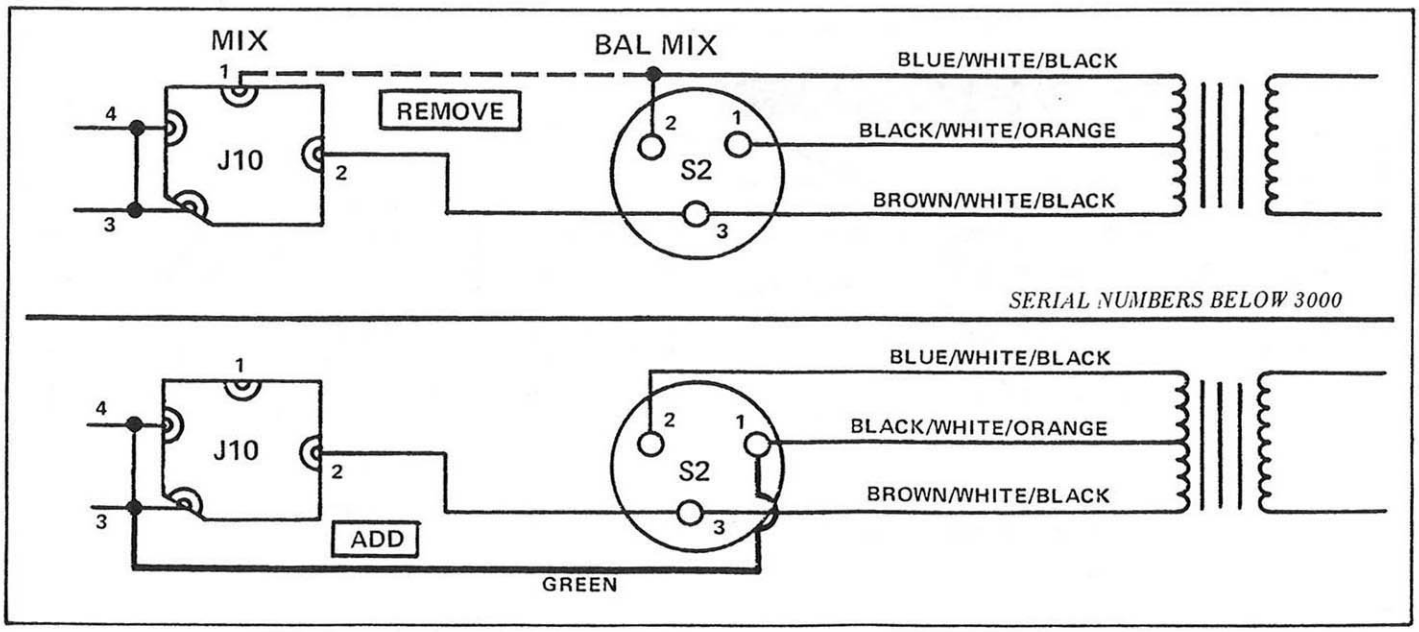

FIGURE 26 MODIFICATION FOR SIMULTANEOUS OUTPUTS (POLYMOOG)

b. To prevent damage to the potentiometer shaft of the external keyboard scale control, shorten it by approximately 1/4-inch (Figure 27). This will ensure that the knob will rest against the mounting hardware and eliminate any stress from damaging the control due to transit or setup of the Polymoog on its rear panel. The control must be removed for this operation. When reassembling the control to the rear panel, add an extra lock washer on the inside as shown if space permits.

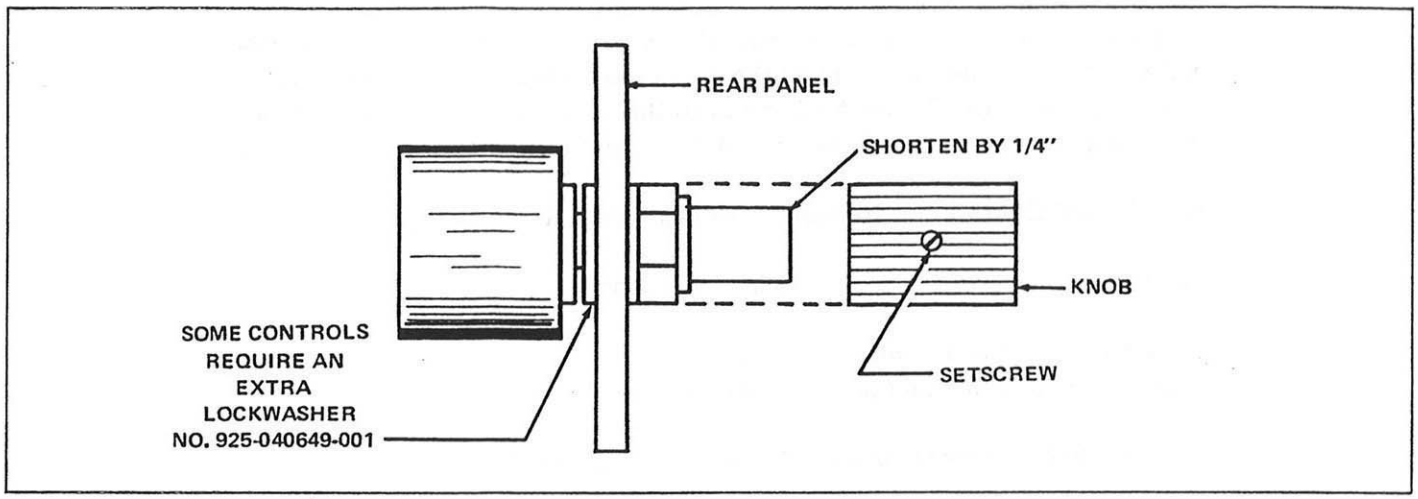

FIGURE 27 EXTERNAL KEYBOARD SCALE CONTROL

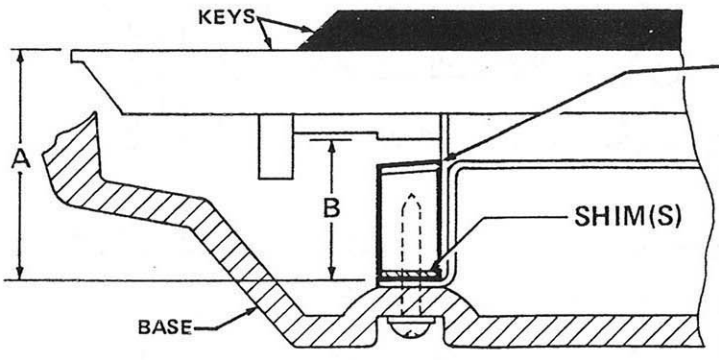
LOCATION: KEYBOARD STOP BAR INSTALLATION. Refer to Figure 28.

NOTE

Keyboard may require adjustment before installing a stop bar. Refer to the keyboard adjustment procedure for details.

Unscrew the keyboard from the case and remove the five Tinnerman fasteners attached to the front edge of the keyboard main frame.



A DIM	B DIM	NO. OF SHIMS REQ'D. (.030)
> 2.015	> 1.285	4
1.980-2.015	1.250-1.285	3
1.945-1.980	1.215-1.250	2
1.915-1.945	1.180-1.215	1
< 1.910	< 1.180	0

NOTE: DELETE TINNERMAN FASTENERS. ADD STOP BAR (978-042580-001) WITH FELT PAD. ADD REQUIRED NUMBER OF SHIMS.

FIGURE 28 KEYBOARD CROSS SECTION

Place one shim on the bottom of the keyboard subassembly where each Tinnerman was removed. This prevents the keys from hitting the case.

Add the stop bar to the keyboard main frame and note that the surface marked FRONT must face outward. Also the felt pad must be in up position.

Add shims between the stop bar and mounting holes as follows:

Depress a white key in the area of a mounting hole.

Bring stop bar up until it touches the depressed key.

Remove paper backing and stick the required number of shims between the stop bar and keyboard frame.

NOTE

Do not over-shim the keyboard stop bar. If a shim prevents the key from traveling all the way down, problems with dynamics will result.

LOCATION: MODULATOR CARDS. Refer to Figure 29.

To improve the dynamics of the keyboard, pad modulator printed circuit boards that sound too loud or too soft. Use the PIANO Preset No. 2 DIRECT output with OCTAVE BALANCE sliders at maximum and also press each key very softly for this test. This adjustment should be performed only after verification of proper supply voltages (+15, -15, +4.85, -5.5), keyboard dynamic adjustments and the keyboard contacts have been adjusted and cleaned as outlined in the service notes.

Using a dB meter, scope, capacitor substitution box, resistor substitution box, and monitor amplifier, add capacitor "C3" to increase the volume (typical values of mylar capacitors are 0.01, 0.022 and 0.033uf maximum) or add resistor "R14" to decrease the volume (typical values are ∞ to 330K). Obtain parts locally for this modification or order a complete set of modulator cards under part number.

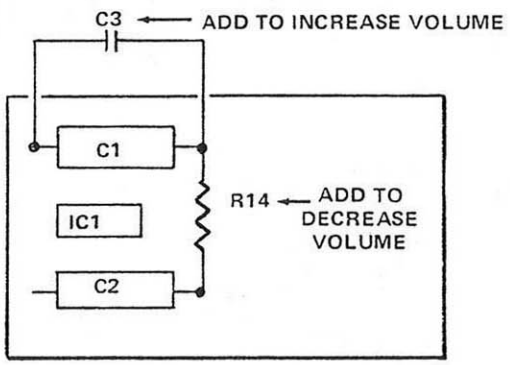


FIGURE 29 MODULATOR CARD (POLYMOOG AND POLYMOOG KEYBOARD)

LOCATION; REAR PANEL STATIC PROTECTION.

Add a 2.7uf tantalum capacitor across SUSTAIN jack (- side to tip, + side to ring).

Install a 10K resistor in series with the BASS output jack (shielded wire).

Use one inch shrink tubing to protect the solder connector.
Add a .01 disc capacitor at the "Bass Output" jack between pin 3 (orange wire) and ground.
Add a 0.001 disc capacitor across MAIN OUTPUT jack between output and ground.

LOCATION: LEFT HAND CONTROL BOARD 10 STATIC PROTECTION. Refer to Figure 30.

Replace jumper wire with 100K resistor R22.

LOCATION: AUDIO BOARD 8 STATIC PROTECTION. Refer to Figure 31.

Replace jumper wire with a 1 megohm resistor R59.

a. Noise Reduction.

Add a 10K resistor R58 with sleeving between the top of R37 and the bottom c
R38.

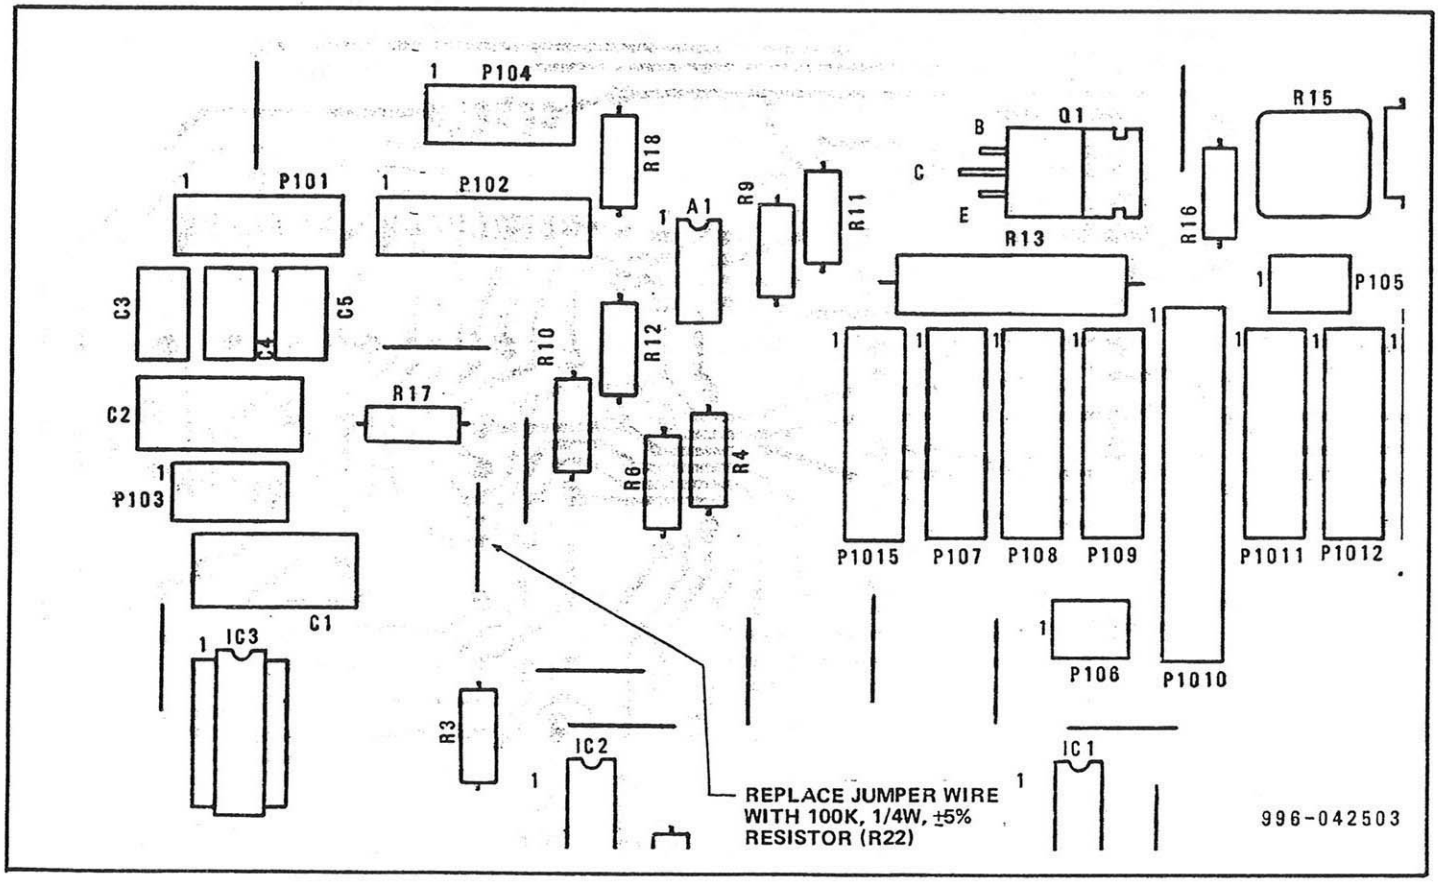

FIGURE 30 LEFT HAND CONTROL CL BOARD 10 (POLYMOOG KEYBOARD)

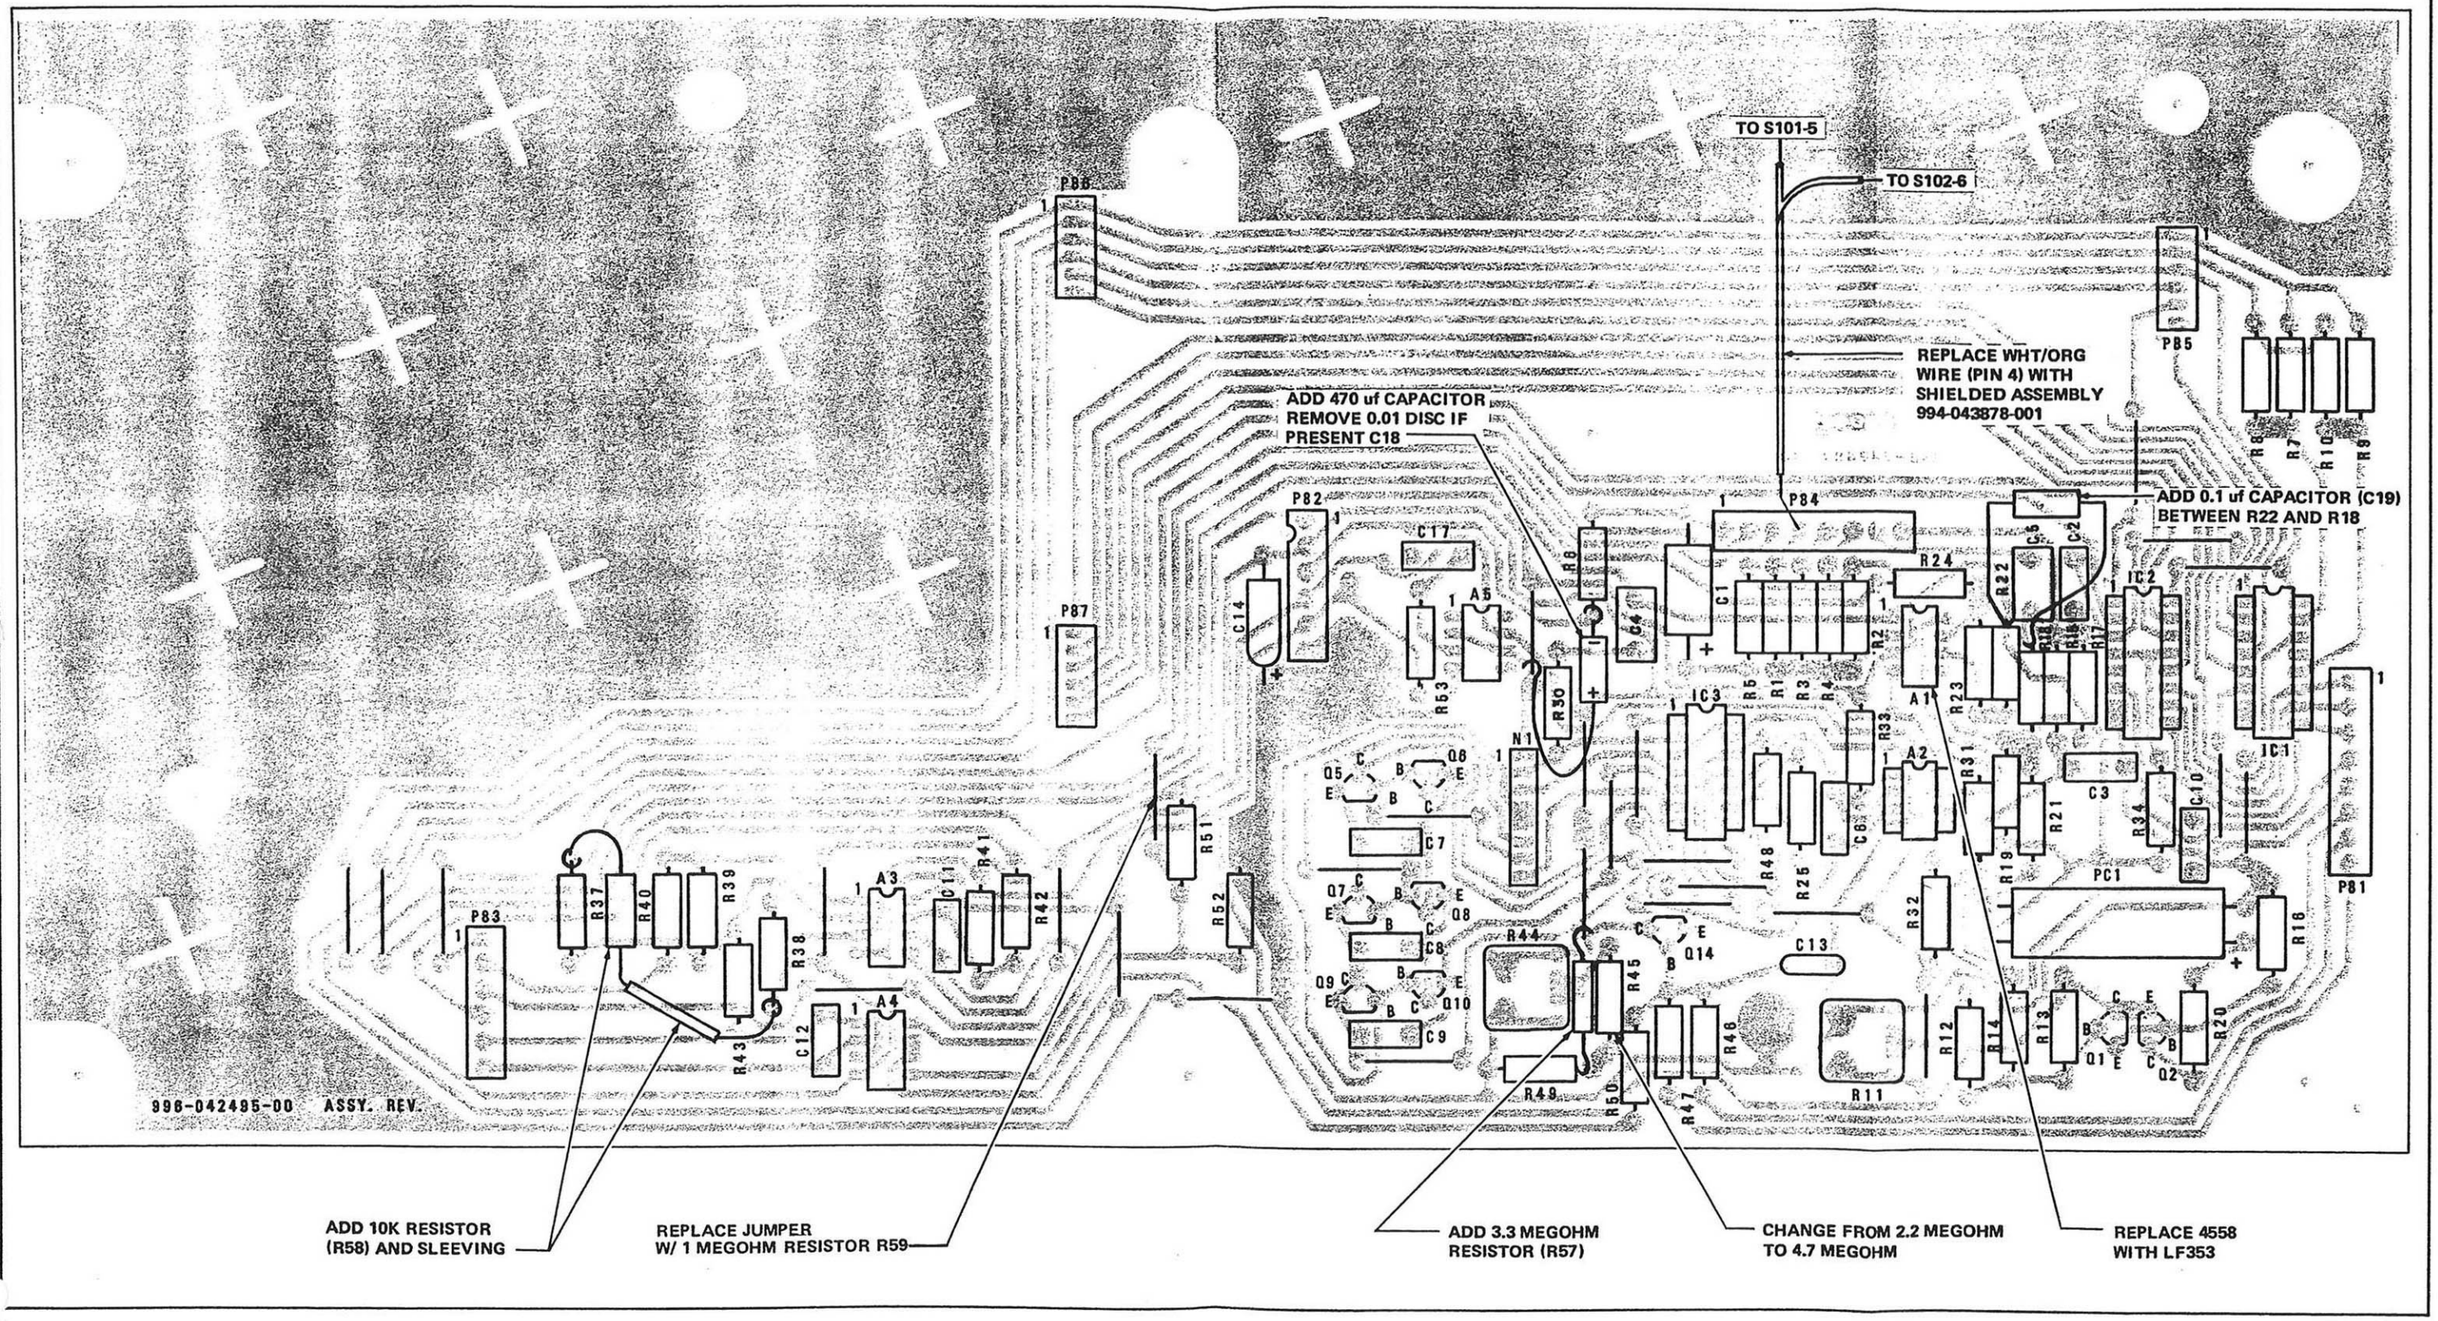

FIGURE 31 AUDIO PRINTED CIRCUIT TC BOARD 8 (POLYMOOG KEYBOARD)

1207-29

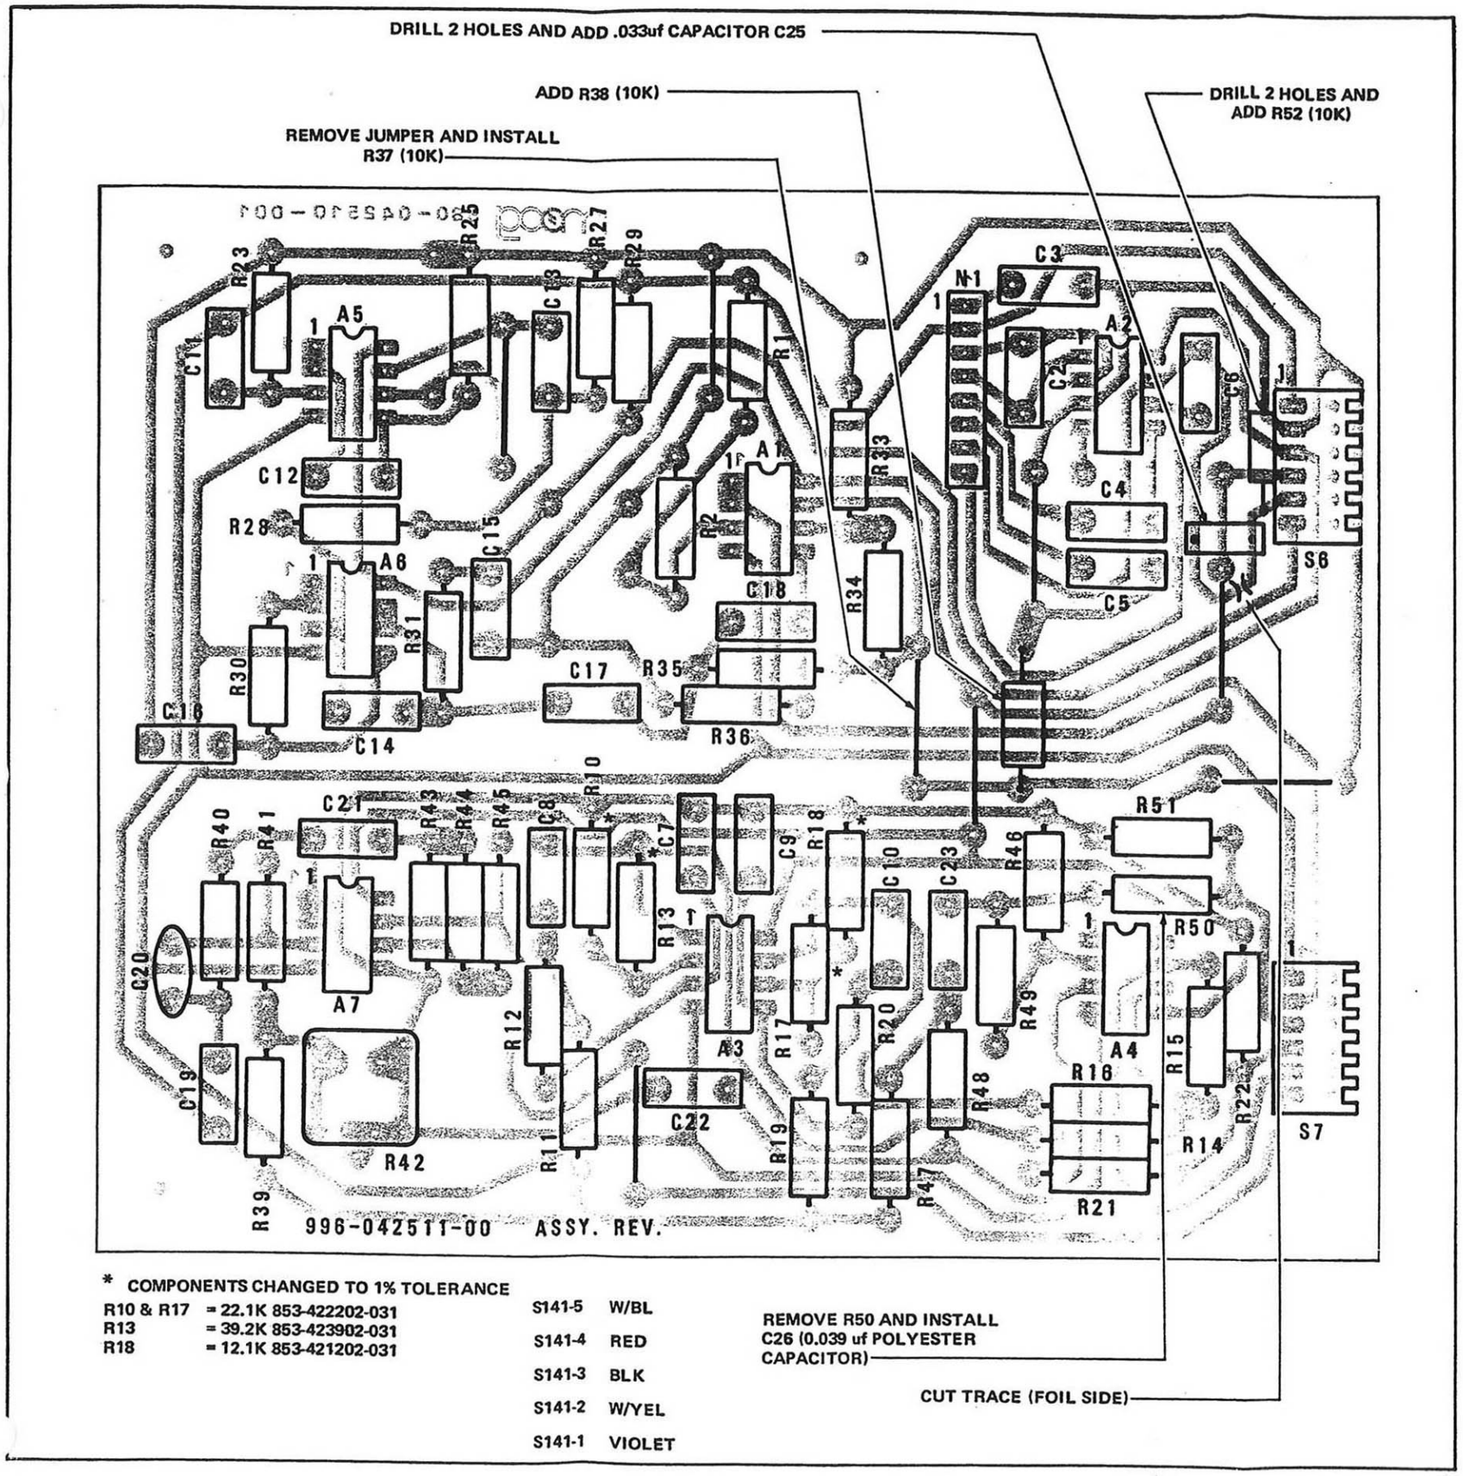

FIGURE 32 FILTER BOARD TC BOARD 8 (POLYMOOG KEYBOARD)

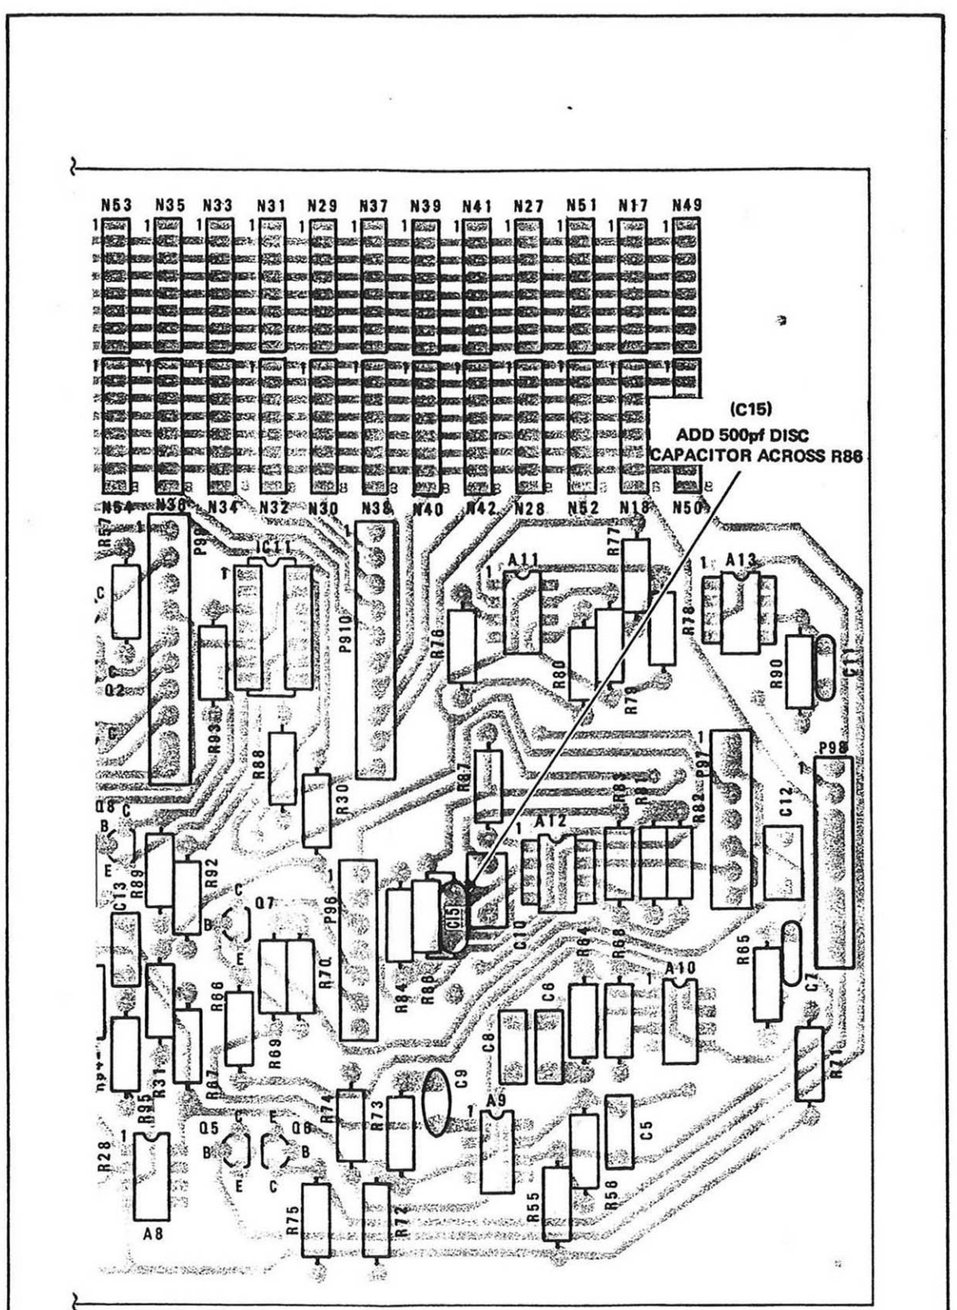

FIGURE 33 PROGRAM CONTROL TC BOARD 9 (POLYMOOG KEYBOARD)

LOCATION: AUDIO BOARD 8 STATIC PROTECTION (Continued)

Add a 470uf 16V electrolytic capacitor C18. Connect negative side to bottom of R6 and plus side to jumper as shown. Tack down with RTV. (Remove 0.01uf capacitor in same position if present.)

Replace A1 with an LF 353 IC instead of a 4558.

Add 0.1uf capacitor C19 between R22 and R18.

Replace white/orange wire between S101-5 and S84-4 with shielded cable assembly 994-043878-001. Connect shield of this assembly to S102-6.

b. Center and Decrease Range of R44 Trim.

Change R45 from 2.2 megohm to 4.7 megohm.

Add 3.3 megohm R57 between right side of R49 and jumper wire.

NOTE

After performing this modification, R44 must be recalibrated.

LOCATION: FILTER BOARD 1. Refer to Figure 32.

a. Update Filter Response Curves.

Replace R10 and R17 with 22.1K ± 1% resistors.

Replace R13 with a 39.2K ± 1% resistor.

Replace R18 with a 12.1K ± 1% resistor.

Replace jumper with 10K R37.

Drill 2 holes and add 10K R52.

Drill 2 holes and add 0.033uf C25. Cut trace as indicated.

Add 10K R38 as indicated.

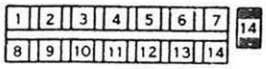
b. Eliminate Thump In Preset No. 13.

Remove R50 and install an 0.039uf polyester capacitor C26 as indicated.

LOCATION: PROGRAM CONTROL BOARD 9. Refer to Figure 33.

a. Eliminate Intermittent Keyboard Circuit Oscillation.

Add 500pf disc capacitor C15 across R86.



LOCATION: FRONT PANEL SUBASSEMBLY. Refer to Figure 24.

a. To Prevent Contact Between The Keyboard And Left Hand Control Board Causing ICs 1 And 2 To Be Forced From Circuit Board.

Glue 2 flat washers between the support clip and the base mounting bracket only if the support clip dimension is 1.280.

LOCATION: POLYPEDAL

1. To prevent loss of control of the PITCH or SWELL pedals, apply Loctite or similar adhesive to the screw as shown and retighten. Refer to Figure 34.

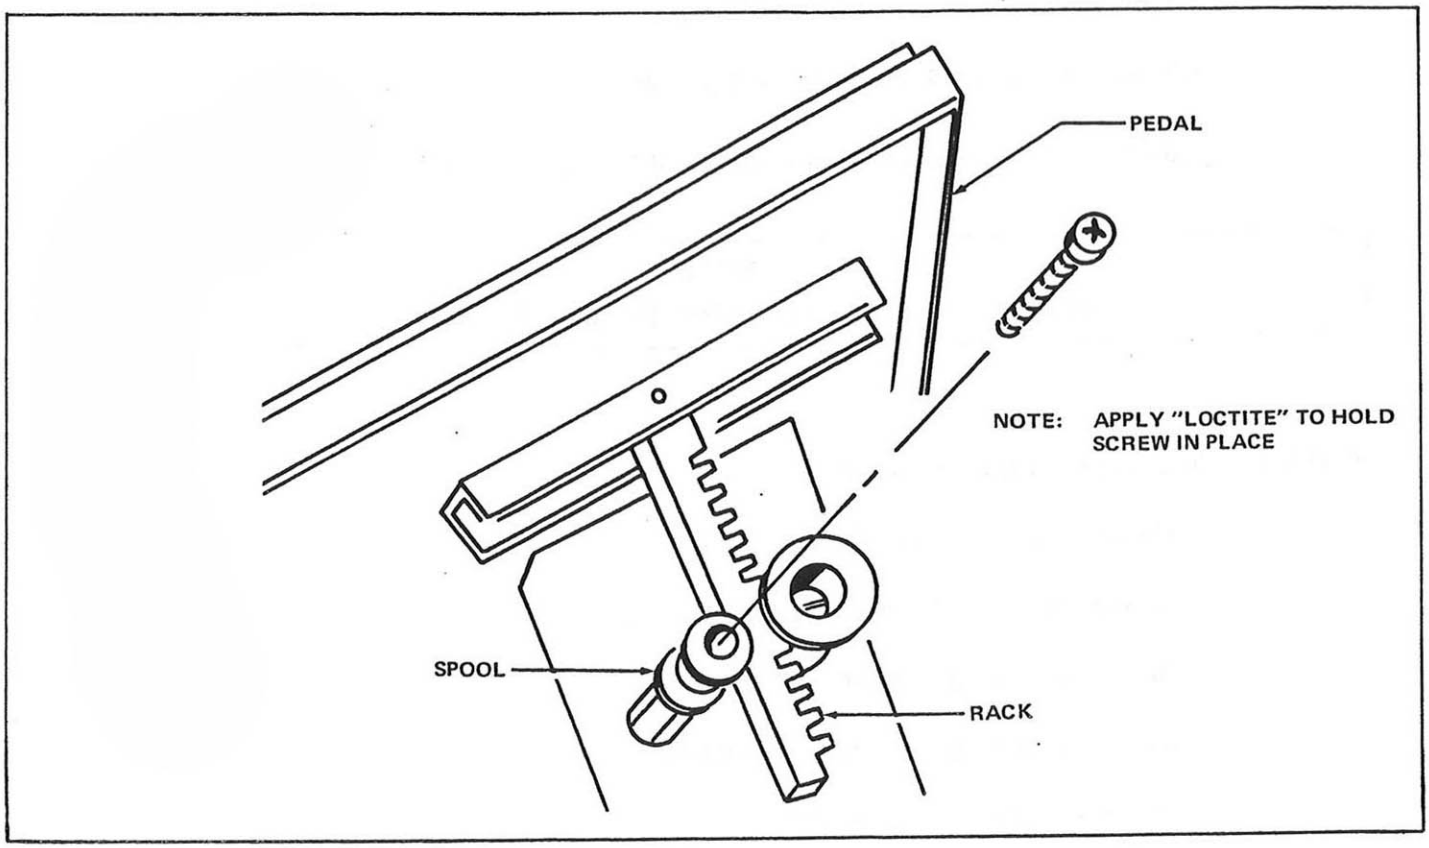


FIGURE 34 POLYPEDAL

SERVICE NOTES

POWER SUPPLY RIPPLE

The two most common causes of excessive power supply ripple are as listed below:

Ducati Electrolytic Capacitors located in the unregulated sections of the power supply have exhibited a short life span. The capacitors dry out which increases ripple on the unregulated voltage and eventually the ripple reaches a point at which the regulator cannot function properly. Typical ripple voltages under normal load conditions in a Polymoog Synthesizer are as follows:

- 15 unregulated section 2.0 volts p/p ripple - read from + side of C1 to ground.
+ 15 unregulated section 2.0 volts p/p ripple - read from + side of C4 to ground.
+ 5 unregulated section 1.3 volts p/p ripple - read from + side of C7 to ground.

A Polymoog power supply will stay in regulation even with half of the bridge rectifier diodes open circuited. The instrument operates normally except for a noticeable "dirty" or "modulated" sounding audio output. If any diode fails, it is recommended that all four (4) diodes in the power supply be replaced.

SLIDEPOTS

When replacing an audio slidepot, note that the same slidepot is used in both audio and reverse audio applications. A reverse audio taper is derived by reversing the connections to the element of the slider and mounting the slidepot upside down.

Exercise care when cleaning slidepots - do not insert a spraying nozzle beyond the protective foam padding as damage may result to the carbon element.

NOTE

On Polymoog Synthesizers above serial number 3000, the decay sliders in the loudness contour section were changed from reverse audio to linear tapers. This was initiated for improved resolution of the decay function when the loudness contour section is switched to the variable state.

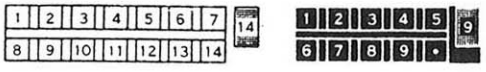
BROKEN KEYCOMB - (Key Pops Up)

This situation requires the replacement of the keycomb which holds the keys in place. There are two keycombs on each keyboard subassembly. One supports 34 keys while the other supports 37 keys. After removing the keyboard subassembly from the unit, tape a stop bar to the top of the keyboard to hold all the white keys down. Place the keyboard face down on a flat, cloth covered surface.

CAUTION

Do not raise the keyboard off the cloth covered surface until all repairs are completed. This ensures that the black keys remain in position during keycomb replacement.

Drill out the rivets securing the broken keycomb. Remove and carefully replace the keycomb and rivet in place.



NOTE

This condition is preventable with the installation of a stop bar for older instruments. Refer to the stop bar instruction procedure in this bulletin.

POLYMOOG AND POLYMOOG KEYBOARD CONTACT ADJUSTMENT PROCEDURE (BELOW SERIAL NO. 3456)

Mechanical tolerances in Polymoog keyboards are very critical for they directly affect keyboard dynamics.

Below is the procedure for properly adjusting the mechanics of the keyboard in field service. Care must be exercised when making these adjustments to prevent damage to the gold plated spring contacts and buss bars. Avoid touching these parts with your fingers to prevent contamination of the gold plated surfaces. It is estimated that this procedure will require an average time of 1.5 hours to complete.

a. Remove the keyboard from the instrument.

b. Place keyboard face down on a table covered with a soft cloth to prevent the keys from being scratched.

c. Using the keyboard adjusting tool as shown in Figure A, line up all "E"s and "D^6" so that the rear spring contact is 1/32 inch (.79 millimeter) behind the rear edge of the concave cutout in the plastic buss bar holders as shown in Figure B. This may be accomplished by extending a taut string across the buss bar holders at the measured distance.

d. Flip keyboard over to the normal playing position. Align all other white keys to be level with the reference keys adjusted in step c. Refer to Figure C. Looking along the front edge of the keyboard, align all black keys so that the lower angle on the black key's front just peeks over the white key surface.

e. Insure that all rocker arms on the underside of the keyboard are in line with each other with no keys depressed.

NOTE

On some black keys the lead weight may be thicker than others. This results in improper contact spacing when the black key is visually lined up as in step d. An out-of-line rocker arm will indicate this problem. Replacing the problem weighted key will correct this condition, but realignment will be necessary.

f. Referring to Figure A, use a .120 inch (3.1 millimeters) gauge and carefully adjust each staple by bending the tube retainers as needed in order that the gauge glides smoothly between the staple and recess buss. A 1/8 inch or number 31 drill bit shank maybe used.

CAUTION

These parts are gold plated and pliers should never contact the staple.

g. Reinstall keyboard, check each note for dynamic response and dirty contacts.

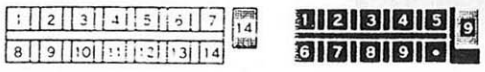
FIGURE C



1207-35

OPERATOR TRAPS (Polymoog Synthesizer and Polypedal)

The following is a checklist of common operator "traps" that result from unfamiliarity with such a complex and flexible synthesizer. This information is particularly useful for:

- A new Polymoog store demonstrator
- A new Polymoog owner and
- A new Polymoog service technician

The accompanying numbered checklist is coordinated with Polymoog front and rear panel diagrams and a Polypedal diagram.

POLYMOOG OPERATOR TRAPS

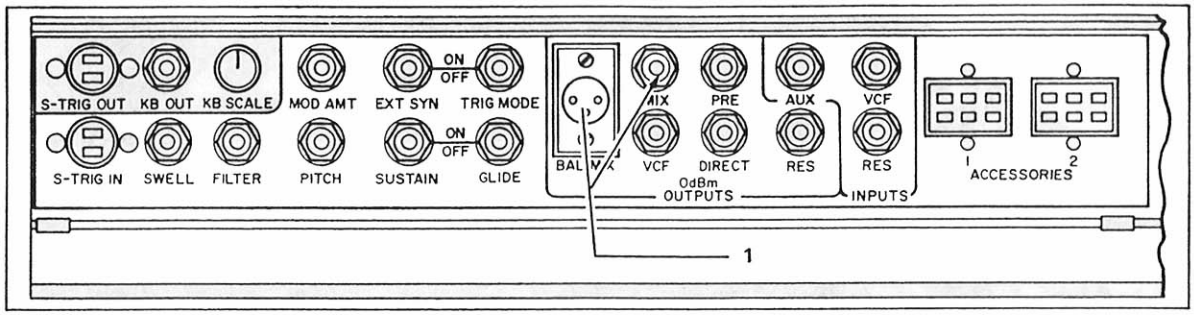


FIGURE 1 REAR PANEL

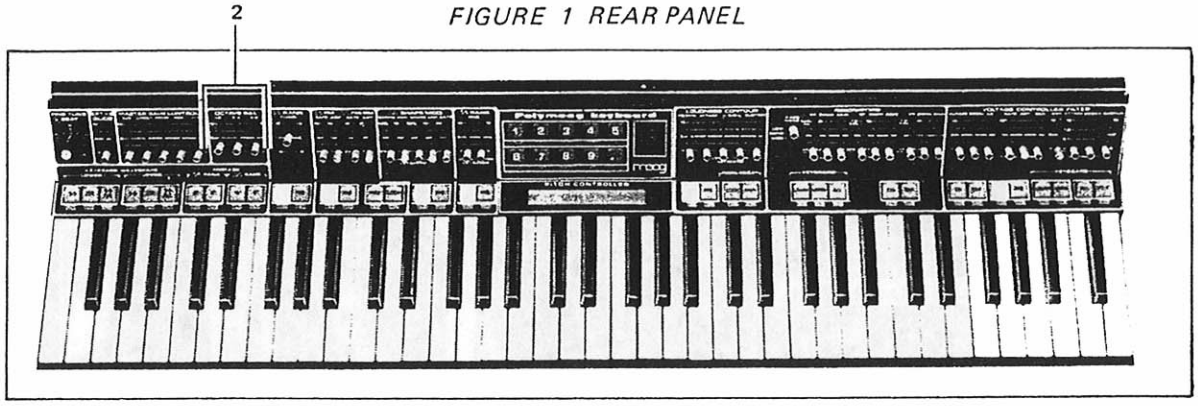

IMAGINED PROBLEM	EXPLANATION OR CORRECTIVE CONTROL SETTING
1. MASTER GAIN CONTROLS not functioning (DIRECT, MODE, RES or VCF)	The Polymoog's BAL MIX (low impedance balanced line) or MIX output should be used.
2. The instrument has a weak and/or noisy output.	The Polymoog's OCTAVE BAL section is designed to control the volume of the three, two octave sections of the keyboard (1-2, 3-4,5-6). The best signal to noise ratio is achieved with all three sliders at 10 (max), or with the section of the keyboard which is to be the loudest set at 10, and the other sections decreased to the desired level. The three sliders should never be set at minimum volume. This will produce a "weak" output signal.

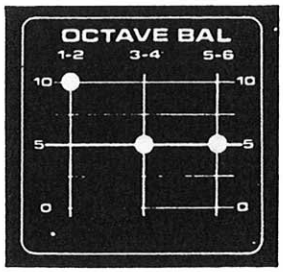

FIGURE 2

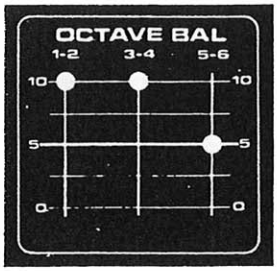

FIGURE 3

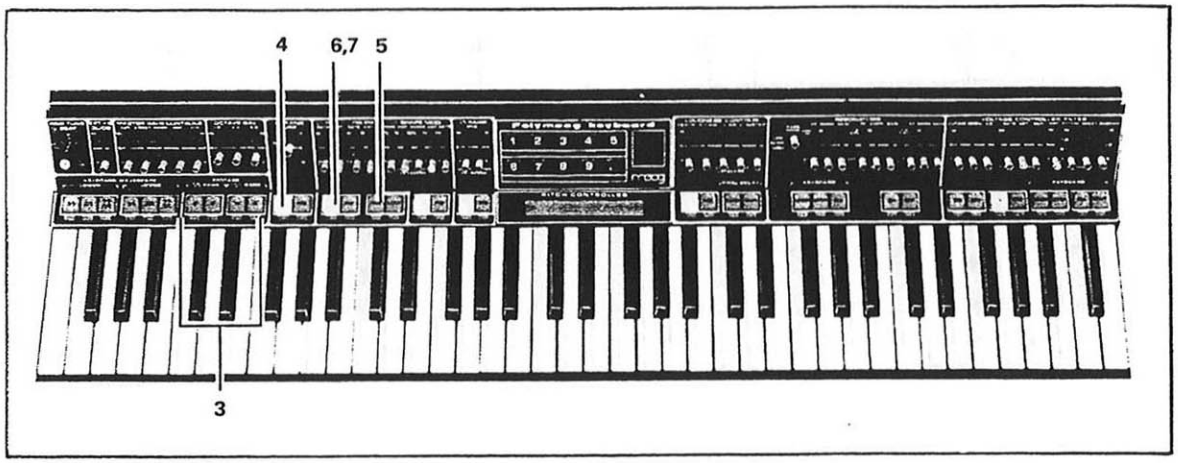

IMAGINED PROBLEM	EXPLANATION OR CORRECTIVE CONTROL SETTING
3. FOOTAGE ⩘ RANK and FOOTAGE ⎍ RANK controls not operating.	The footage (octave) of the preset voice selected must coincide with the appropriate waveshape. For example, BRASS (Preset No. 8) uses only the sawtooth waveshape. Changing the footage of the square rank will produce no audible effect, since the square waveshape is not on. Refer to the LED's in the Keyboard waveshape section to determine which waveshapes the preset voice uses. If the preset does not use that waveshape, press the button of the waveshape to activate it and then alter the footage for that waveshape.

FIGURE 4

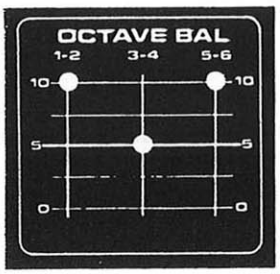

FIGURE 5

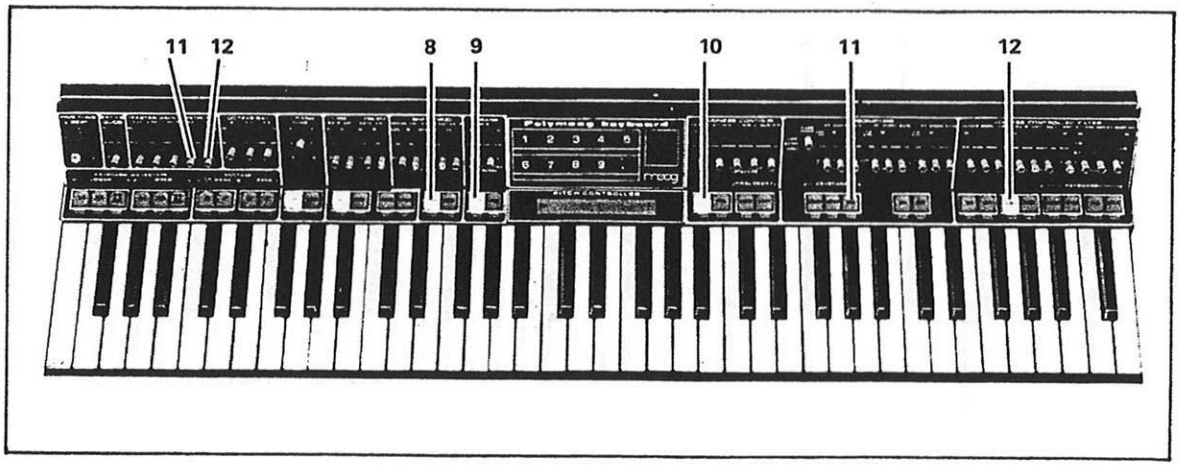
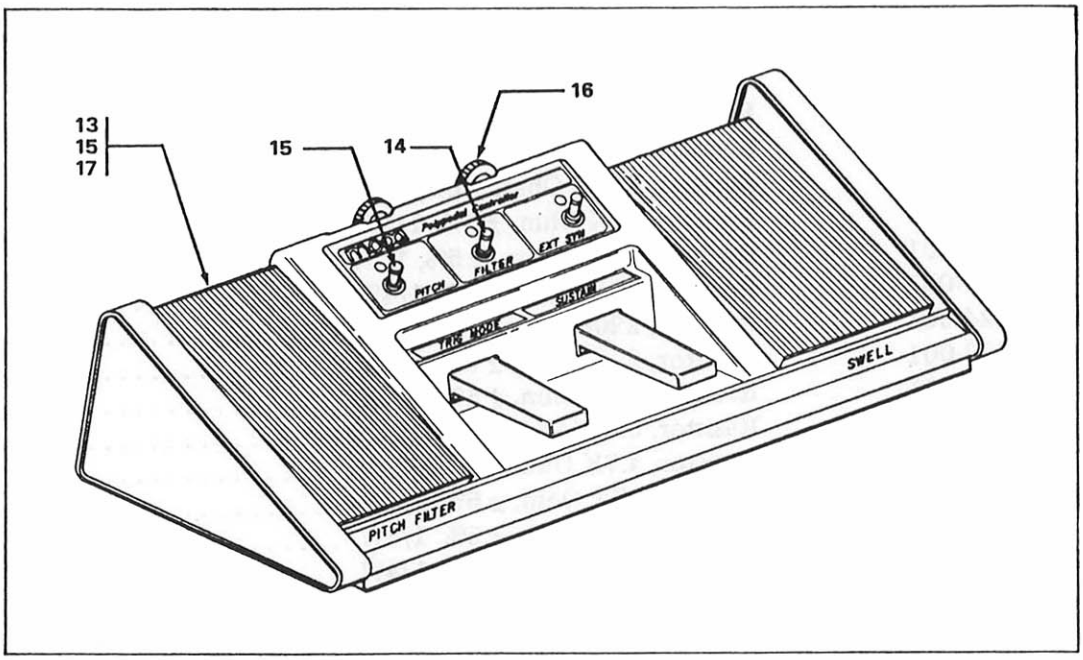
4. ⩘ RANK TUNE control inoperative.	The VAR button must be pressed to activate this control. The sawtooth waveshape must be on to control its pitch. Refer to the LED's in the keyboard waveshape section. Secondly, both keyboard waveshapes (sawtooth and square) must be on to be able to tune one pitch against another for intervals and the waveshapes must be unlocked by pressing the FREE button for presets 2, 4, 5, 6 and 7.
5. BEAT control not functioning.	The BEAT control finely detunes the square waveshape from the sawtooth. Both waveshapes must be on, and in the case of presets 2, 4, 5, 6 and 7, the FREE button must be pressed to unlock the waveshapes.
6. ⩘ FM control inoperative.	The VAR button must be pressed. Check if preset used sawtooth waveshape.
7. ⎍ FM/PM control inoperative.	The VAR button must be pressed. Check if preset uses square waveshape.



IMAGINED PROBLEM	EXPLANATION OR CORRECTIVE CONTROL SETTING
8. Square Waveshape Modulation section inoperative.	The VAR button must be pressed. Check if preset uses square waveshape. If the SHAPE sliders are set at maximum 50%, no modulation varies the waveshape from narrow to full. At 50%, the waveshape is starting at full and cannot be made any wider.
9. ⩘ RANK MIX control not functioning.	This controls the volume of the sawtooth waveshape. The VAR button must be pressed. Check if the preset voice uses sawtooth waveshape.
10. LOUDNESS CONTOUR inoperative.	The VAR button must be pressed. If the ATTACK slider is set higher than the DECAY sliders (with no sustain), no sound will result.
11. RESONATORS section inoperative.	The RESONATOR and MASTER GAIN CONTROLS must be turned up. At zero, no signal from the resonators is present. KEYBOARD ALL button must be pressed to hear the entire keyboard. Make sure the OFF button has not been pressed. The individual RESONATOR GAIN controls must be up for the resonator section to operate. If the EMPHASIS and GAIN sliders in any one section are both at maximum, distortion may occur in the low-pass and band pass modes.
12. VOLTAGE CONTROLLED FILTER section inoperative.	The VCF MASTER GAIN CONTROLS must be raised. At zero, no signal is present. The VAR button must be pressed. Make sure the OFF button has not been pressed. See Polypedal sectior also.

THE POLYPEDAL AND ITS INTERACTION WITH THE POLYMOOG



IMAGINED PROBLEM	EXPLANATION OR CORRECTIVE CONTROL SETTING
13. VOLTAGE CONTROLLED FILTER CONTOUR is not operating.	The PITCH FILTER pedal must not be at maximum. At maximum, the filter cutoff is at 10 and cannot be contoured.
14. PITCH FILTER is being used to control the filter and no effect is heard.	The FILTER on/off switch must be "on." LED glows when the switch is "on."
15. PITCH FILTER pedal is being used to control pitch.	The PITCH on/off switch must be "on." LED glows when the switch is "on."
16. No pitch change occurs.	A rotary pot controls the pitch-bend range of the pedal. It must be set above zero for pitch change to occur.
17. Signal distortion occurs with use of PITCH PEDAL.	On Polymoogs under serial number 3000, if the pitch pedal and pot are both at maximum, signal distortion can occur. Since the range this cumulative effect produces is extremely high-pitched, in most cases, backing off the rotary pot slightly will not affect musical performance.

PRESET VOICING KIT

PART NO. 997-043991-001

PART NO.	DESCRIPTION	QTY
852-312105-001	Resistor, 1 Megohm, ± 5%, 1/4W	2

STANDARD NOISE FILTER SCHEMATIC

POLYMOOG NOISE TEST

NOISE

Set up the Polymoog as follows:

Preset 2.	PIANO
Rectangular only.	
MASTER GAIN CONTROLS:	In full down position.
SHAPE, MOD, VAR:	SHAPES in full up position, RATES and AMT in full down position.
LOUDNESS CONTOUR VAR:	All pots in full down position except SUSTAIN in full up position.
RESONATORS:	Low pass – All pots in full down position except place HIGH GAIN in full up.

Check for maximum output level from DIRECT, MODE and VCF of +4 ± 2dBm each when depressing A4 and +8 ± 2dBm from resonators. Then make the following noise checks in each preset. The MASTER GAIN Control for the output under test should be full up, all other MASTER GAIN Controls full down. The noise is specified as a maximum voltage level on the Hewlett Packard Model 400F voltmeter (or equivalent). Check level at unbalanced MIX Out and individual output under test.

PRESET NOISE CHECKS		MIX OUTPUT	INDIVIDUAL OUTPUT
1. STRING	(a) MODE	- 82	- 80
	(b) DIRECT	- 81	- 78
	(c) VCF	- 74	- 72
2. PIANO	(a) MODE	- 72	- 78
	(b) DIRECT	- 82	- 80
	(c) VCF - hit top key	- 74	- 73
3. ORGAN	(a) MODE	- 77	- 75
	(b) DIRECT	- 81	- 78
	(c) VCF	- 74	- 74
4. HARPSICHORD			
	(a) MODE	- 80	- 81
	(b) DIRECT	- 72	- 73
	(c) VCF	- 75	- 74
5. FUNK	(a) MODE	- 70	- 68
	(b) DIRECT	- 79	- 80
	(c) VCF - splits on S and H	- 72	- 73
6. CLAVINET	(a) MODE	- 71	- 70
	(b) DIRECT	- 80	- 79
	(c) VCF	- 70	- 68

PRESET NOISE CHECKS		MIX OUTPUT	INDIVIDUAL OUTPUT
7. VIBES	(a) MODE	- 72	- 75
	(b) DIRECT	- 80	- 79
	(c) VCF	- 72	- 73
8. BRASS	(a) MODE	- 80	- 79
	(b) DIRECT	- 83	- 82
	(c) VCF	- 77	- 75

RESONATORS - NOISE CHECKS

1. All pots down in RES and in MASTER GAIN	- 81
2. All pots down in RES, lowpass; MASTER GAIN up	- 80
3. All pots up in RES, lowpass; MASTER GAIN up	- 55
4. All pots up in RES, highpass; MASTER GAIN up	- 57
5. All pots centered, MASTER GAIN up, bandpass	- 75

RESIDUAL NOISE CHECK

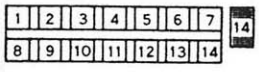
All pots down – Preset 1 strings

MIX	- 90
VCF	- 84
DIRECT	- 84
MODE	- 84

Also depress a note and check for no residual output with all pots down.

NOISE: Connect AC voltmeter to the appropriate output and check for the following maximum noise levels (dBm):

PRESET NUMBER	DIRECT	MAIN	BASS
1. VOX HUMANA	-78	-84	-72
2. STRING 1	-82	-81.5	-78
3. STRING 2	-79	-83	-73
4. ELECTRIC PIANO	-83.5	-81	-81
5. PIANO	-83.5	-80	-82
6. HONKY TONK PIANO	-83	-81.5	-79
7. CLAV	-82	-81	-78
8. HARPSICHORD	-78	-83	-73
9. BRASS	-84	-77	-84
10. BRASS CHORUS	-84	-76	-81
11. PIPE ORGAN	-83	-83.5	-78
12. ROCK ORGAN	-79	-83.5	-75
13. VIBES	-82	-78	-79
14. FUNK	-82	-79	-78



POLYMOOG SYNTHESIZER
FINAL TEST AND INSPECTION CHECKLIST

1. MECHANICAL INSPECTION

☐ Remove Any Loose Foreign Material From Unit Interior
☐ Cover, Leg Brackets
☐ Feet and Truss Bar Knobs
☐ Keyboard Mounting Screws
☐ Trim Strips in Place

2. POWER SUPPLIES

☐ +15V ☐ -15V ☐ +5V
☐ +4.85V ☐ -5.5V (All ± 0.010V)

3. MASTER OSCILLATOR TUNING

☐ A440

4. MODE PRESET VOICES

☐ All Voices Correct
☐ Preset 9 Switches All Functions to Variable
☐ Part/Full Retains All Variable Functions When New Preset is Selected
☐ All Notes Working on All Presets
☐ Noise Levels Acceptable

5. RESONATOR CONTROL SECTION

☐ Slide Controls
☐ Pushbutton Controls
☐ All Voices Correct

6. VCF CONTROL SECTION

☐ Slide Controls
☐ Pushbutton Controls
☐ All Voices Correct

7. DIRECT OUTPUT

☐ Sawtooth
☐ FM
☐ 8′ 4′ Combination
☐ RANK MIX (Upper and Lower)
☐ RANK TUNE
☐ OCTAVE BALANCE

7. DIRECT OUTPUT (Continued)

☐ ⎍⎍⎍ Rectangular
☐ 16′ 8′ Combination
☐ FM/PM
☐ Lock

8. SHAPE AND MODULATION CONTROL SECTION

☐ SHAPE - Upper and Lower
☐ MOD Amount - Upper and Lower
☐ RATE - Upper and Lower

9. RIBBON CONTROLLER

☐ Zero Pitch Change Before And After Use
☐ Centering
☐ Oscillator Tracking
☐ Smoothness of Appearance

10. LOUDNESS CONTOUR CONTROL SECTION

☐ Slide Controls
☐ Final Decay - Each Note

11. MODULATOR CARD LEAKAGE

☐ No Bleedthrough After 30 Seconds

12. KEYBOARD

☐ Feel
☐ On Each Key
☐ ⎍⎍⎍ On Each Key
☐ Dynamic Consistency 3dB Between Notes and 6dB Overall
☐ Dynamics Range and Response to Rapidly Repeated Triggering and Decay Uniformity

(Checks for Cleanliness, Contact Spacing and Backwrap)

POLYMOOG SYNTHESIZER
FINAL TEST AND INSPECTION CHECKLIST (Continued)

12. KEYBOARD (Continued)

☐ Overall Keyboard Response to Fast Runs

13. REAR PANEL

☐ RESONATOR In, VCF In, and AUX In
☐ S-TRIG In/Out
☐ TRIG MODE
☐ GLIDE ON/OFF
☐ SUSTAIN ON/OFF
☐ EXT SYN ON/OFF
☐ SWELL
☐ MOD AMOUNT
☐ PITCH, External Oscillator
☐ VCF
☐ Keyboard Control Voltage Out

POLYMOOG KEYBOARD
FINAL TEST AND INSPECTION CHECKLIST
(Compare Voicing to Another Polymoog or Tape Cassette)

1. MECHANICAL INSPECTION

☐ Remove any Loose Matter from Unit Interior
☐ Ensure All Boards are Properly Secured
☐ Cover
☐ Truss Bar Knobs (If Available)
☐ Feet
☐ Keyboard Mounting Screws
☐ Trim Strips
☐ Ribbon Smoothness

2. POWER SUPPLIES

☐ +15V ☐ -15V
☐ +5V (All ± 0.010V)

3. NOISE, FEEL, TUNING AND APPEARANCE

☐ Power Switch
☐ Slide Pots
☐ Controls, Switches and LEDs
☐ Oscillator Tuning - Fine Tune and Beat ± 0.25

4. PRESET NO. 1 VOX HUMANA

☐ Output from Each 2 Octave Section
☐ Proper Voicing
☐ ATTACK 0 - 10
☐ MODULATION AMOUNT 0 - 10
☐ MODULATION RATE 0 - 10
☐ Beat Rate is Variable
☐ Noise

5. PRESET NO. 2 STRING 1

☐ Output from Each 2 Octave Section
☐ Proper Voicing
☐ ATTACK 0 - 10
☐ MODULATION AMOUNT 0 - 10
☐ Beat Rate is Variable
☐ Noise

6. PRESET NO. 3 STRING 2

☐ Output from Each 2 Octave Section
☐ Proper Voicing
☐ SUSTAIN ON/OFF

6. PRESET NO. 3 STRING 2 (Continued)

- ☐ ATTACK 0 - 10
- ☐ MODULATION AMOUNT 0 - 10
- ☐ Beat Rate is Variable
- ☐ Noise

7. PRESET NO. 4 ELECTRIC PIANO

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Noise

8. PRESET NO. 5 PIANO

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Noise
- ☐ Dynamic Consistency. 3dB Between Notes and 6dB Overall
- ☐ Dynamic Range and Response to Rapidly Repeated Triggering and Decay Uniformity

(Checks for Cleanliness, Contact Spacing and Backwrap)

- ☐ Overall Keyboard Response to Fast Runs

9. PRESET NO. 6 HONKY TONK PIANO

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Beat Rate is Variable
- ☐ Noise

10. PRESET NO. 7 CLAVINET

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Noise

11. PRESET NO. 8 HARPSICHORD

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Beat Rate Variable
- ☐ Raise Pitch One Octave with Pedal. Check for Normal Output of ⩘ and ⎍ Waves.
- ☐ Noise

12. PRESET NO. 9 BRASS

- ☐ Output from Each 2 Octave Section
- ☐ Control of VCF Cutoff Frequency with Pedal
- ☐ Proper Voicing
- ☐ Single - Multiple Trigger of VCF with Rear Panel Switch
- ☐ SUSTAIN ON/OFF (Very Short)
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10

POLYMOOG KEYBOARD
FINAL TEST AND INSPECTION CHECKLIST (Continued)
(Compare Voicing to Another Polymoog or Tape Cassette)

12. PRESET NO. 9 BRASS (Continued)

- ☐ Bass Filter ON/Off
- ☐ Bass Level and Cutoff 60Hz - 300Hz
- ☐ Octave Balance Sliders
- ☐ Swell Range 28dB
- ☐ Volume Slider
- ☐ Fine Tune
- ☐ ⩘ Presence and Clarity Each Note
- ☐ Ribbon Smoothness of Performance
- ☐ Ribbon Does Not Affect Pitch Before and After Use
- ☐ Ribbon Centering and Range
- ☐ Noise

13. PRESET NO. 10 BRASS CHORUS

- ☐ Ribbon Oscillator Tracking with Modulation Amount at 0
- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF (Very Short Sustain)
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ ATTACK 0 - 10
- ☐ Noise

14. PRESET NO. 11 PIPE ORGAN

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ ATTACK 0 - 10
- ☐ Noise

15. PRESET NO. 12 ROCK ORGAN

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Noise

16. PRESET NO. 13 VIBES

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ ⎍⎍⎍ Presence and Clarity Each Note With MODULATION OFF
- ☐ Noise

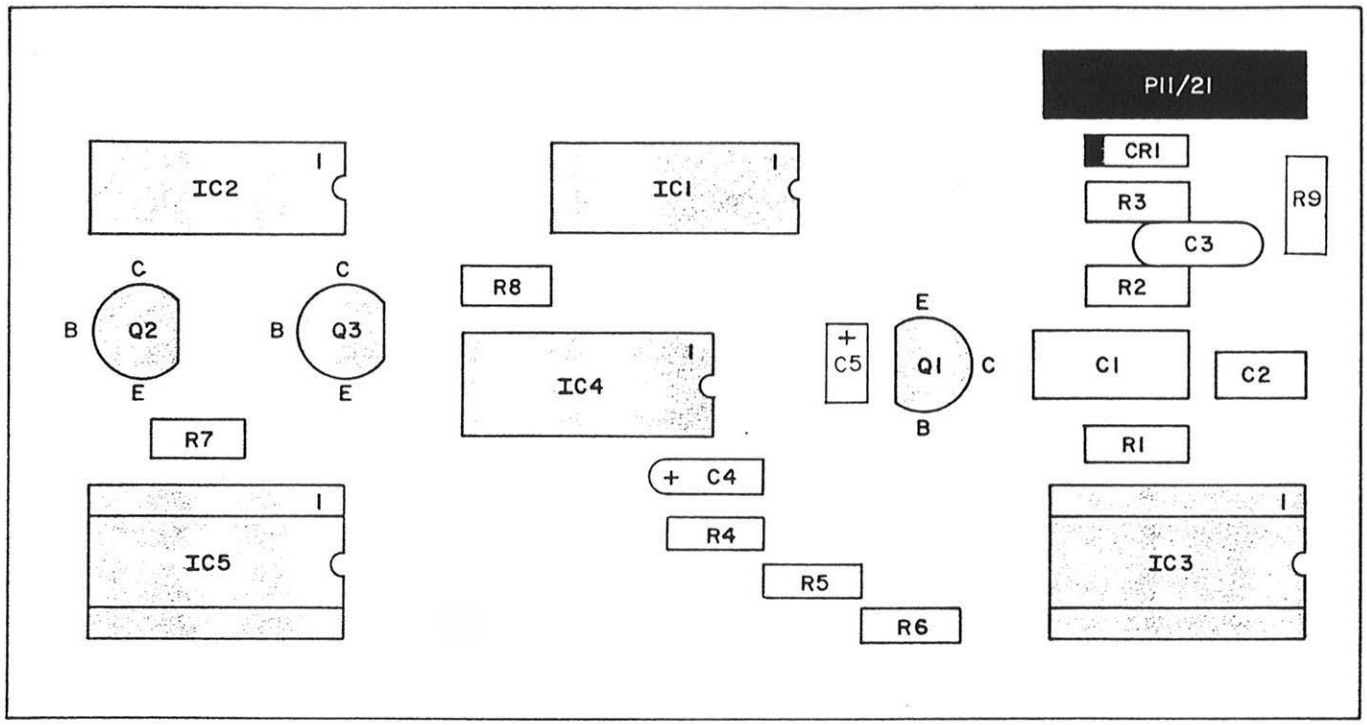
17. PRESET NO. 14 FUNK

- ☐ Output from Each 2 Octave Section
- ☐ Proper Voicing
- ☐ SUSTAIN ON/OFF
- ☐ MODULATION AMOUNT 0 - 10
- ☐ MODULATION RATE 0 - 10
- ☐ Noise

18. FINAL CHECK

- ☐ Power Supply Voltages
- ☐ Oscillator Tuning

NOTE:
REFER TO THE REPLACEMENT PARTS LIST IN VOLUME 1, SECTION 2 FOR THE PART NUMBER AND DESCRIPTION OF EACH REFERENCE DESIGNATOR.



REV	DESCRIPTION	EO
A	REVISED FOR C-B KEYBOARD	
B	REVISED FOR F-E KEYBOARD	
C	RELEASED FOR PRODUCTION	0192
D	CHANGED R3 FROM 1.3K TO 1.8K	0388
E	CHANGED R3 FROM 1.8K TO 1.8K-3.3K SELECTED	0420
F	ADDED PII WIRE DESTINATIONS	0617
G	ADDED TANT. CAPACITOR C5 1.5UF/20V	0630

REV	DESCRIPTION	EO
A	ADDED 1K RESISTOR TO PIN 19	
B	RELEASED FOR PRODUCTION; ADDED (2) 1N4148 DIODES CR1 AND CR2	0192
C	CHANGED C1 FROM .1/100V METAL MYLAR TO .12/50V ± 5%	0663
D	NEXT ASSEMBLY WAS 981-040147	4790
E	CHANGED R6 FROM 24K, 5% TO 24.3K, 1% MF AND CHANGED R13 FROM 51K, 5% TO 49.9K, 1% MF.	0892

NOTES:
UNLESS OTHERWISE SPECIFIED.
1. ALL RESISTOR VALUES ARE IN OHMS 1/4W, ± 5%.
2. ALL CAPACITOR VALUES ARE IN MFD (uf) ± 10% METALLIZED MYLAR.
3. ALL DIODES 1N4148.
4. USING A DB METER, SCOPE, CAPACITOR SUBSTITUTI BOX, RESISTOR SUBSTITUTION BOX, AND MONITOR AMPLIFIER IT IS POSSIBLE TO CHANGE THE DYNAMI RESPONSE OF LOW OR LOUD SOUNDING MODULATO CARDS. THIS ADJUSTMENT SHOULD BE PERFORMED AFTER PROPER SUPPLY VOLTAGES (+15, -15, +5, +4.8 -5.5). KEYBOARD DYNAMIC ADJUSTMENT (VOL. 1, P. STEPS T, U AND V), AND AFTER THE KEYBOARD CONTACTS HAVE BEEN CHECKED AND CLEANED AN SPACED TO .120 GAGE INCHES (1/8 INCH DRILL BIT).
5. CAPACITOR C3 RAISES THE VOLUME (TYPICAL VALU OF MYLAR CAPACITORS COULD BE .01, .002 AND .00 (uf) MAXIMUM.
6. RESISTOR R14 DECREASES THE VOLUME (TYPICAL VALUES: 330K TO ∞).
7. C1 AND C3 REPLACED WITH ONE .12uf CAPACITOR I LATER PRODUCTION.
